Assuming the power function of —0.5 cited above, it can be shown that the total radiation dose accumulated at any time is equal to twice the time multiplied

by the burden. Taking the mass of the skeleton as 7 kilograms, some accumulated dosages are given in Table II.

Strontium 90—Radium Comparison.—Data on late toxicities of strontium and radium in small animals have indicated that a factor of 10 on an energy basis is roughly correct. This would suggest that alpha and beta radiations are relatively equivalent in terms of energy. This may be approximately correct, although the relative biological effectiveness of alpha radiation to x-ray of 10 is presently assumed in calculating permissible doses where experimental data are lacking.

Relative Biological Effectiveness (RBE), Alpha and Beta Rays.—Alpha rays from slow neutron absorption in animals containing boron, have indicated that a factor of 1.4 relative to X rays is roughly correct. Experiments with inhaled radon and injected radon show factors of 1.4 to 1.5 for acute effects, and 3.0 for chronic effects. The RBE for mice seems to pass through a maximum around the ionization density of fast neutrons. Observations on yeast also show a maximum in the intermediate range. The consensus is that a radium to strontium-90 factor of 10 may be a little low but not as low as it was formerly assumed. It was agreed by the Subcommittee to calculate radium and strontium both in roentgen equivalents for the present, although this may give strontium a small additional factor of safety over radium.

Absorption of Strontium.—There are considerable variations in the degree of absorption of strontium depending on the contents of the gastrointestinal tract and the demand for calcium. Absorption of radiostrontium by plants has been investigated, and it appears that the uptake is relatively independent of the concentration of carrier; in other words, it is taken up as a contaminant of the water absorbed. This breaks down only at high levels, where radiation effects on the physiology of the plant enter in. Under fallout conditions, it may also be deposited on leaves. Experiments have indicated that, under a variety of conditions, between one and ten per cent of the strontium-90 in the soil is available to a crop of plants. About five per cent of the strontium taken up by the plants is then retained by animals foraging on them after two to four weeks.

Data on the actual stronium-90 content of biological materials and human beings as a result of past and present fallout have indicated that human bones have now reached an amount equal to one-thousandth of a microcurie (that is, of presently accepted permissible human skeletal content) in young children, declining to approximately zero in persons above 40 years of age. Such calcium-rich sources of the isotope as cheese and milk yield values which are higher in respect to the Sr^{90} : calcium ratio.

Another way of looking at the same question is to consider uptake. When this is done, it appears that the strontium retention in man from the diet is 0.3 to 0.6 times what it would be if strontium were an ideal tracer for calcium.

Radioiodine.—Under existing fallout conditions, cattle in Tennessee have shown up to 10^{-3} $\mu c/gm$ of thyroid, but human thyroids have not shown more than 1/100 of this concentration. External counts on monitors in the Nevada test areas have shown not more than 10^{-4} $\mu c/gm$ of thyroid, with all probabilities in favor of a smaller concentration. In view of the short half-life of I-131 it can be concluded that the hazard of bomb tests from this standpoint is negligible.

It has been suggested that the human thyroid is less radio-sensitive than other tissues, such as bone, since after many years of treatment of Graves' disease with radioactive iodine, no cases of resulting carcinoma have been reported. The customary dosages of I^{131} in such cases yield at least 4000 rep to the gland. On the other hand, carcinoma of the thyroid found in children and young adults has almost invariably been preceded by x-ray treatment to the upper part of the body, in amounts such as to yield as little as 200 r to the infant thyroid. It has been estimated that less than 3% of such treated cases yield carcinoma; nevertheless, the data suggest that 200 r is a potentially carcinogenic dose to the infant thyroid. While the possibility exists that the carcinogenic action may be an indirect, hormonal one, it must still be recognized that this, like leukemia, is an instance of significant carcinogenesis by less than 1000 rep. It seems likely that the infant thyroid is unduly suspectible, but that the adult thyroid is not.

Radiation from Particles and Hot-Spots.—One matter which has caused some concern is the effect of intense radiation of a few cells from particulate sources of radiation.

The only available experimental evidence that bears on this question is an experiment in which the skin was irradiated with beta rays, diffusely over the surface, and by point sources yielding the same amount of radioactivity. It was shown that the point sources were considerably less efficient.

In the case of the skeleton in chronic radium or radiostrontium poisoning, a large part of the dose is from the hot-spots due to concentration of the radioactive material in a few haversian systems that were forming at the time the radioelement was administered. All of the integrated skeletal dosages shown in table 2 (except from X rays, where the bone dose is about four times the air dose given) must therefore be looked at with the consideration that the maximal dose in these hot areas is about ten times as great as the average.

Permissible dosage to Large Populations.—This is a matter on which no complete agreement was reached by the Subcommittee. First responses to this question ranged all the way from the permissible industrial level down to no radiation at all. The uncertainty existing here stems from our ignorance as to whether there is a true threshold for such late effects as malignant tumors, and as to the degree of variation in response to equally exposed individuals.

It was agreed that the only rational approach must take into account the natural radiation background to which the population is exposed. Figures on this, from various sources, are given in table II. It is noteworthy that considerable differences exist from place to place, due mainly to differences in gamma radiation from the environment, and in part to variations in radium content of individuals. Since these existing variations have not given rise to any changes in incidences of tumors or other pathologic states sufficient to attract attention, it was felt that an amount of internal radiation sufficient to double the large population background could certainly be considered safe.

Part B of table II shows integrated skeletal radiation dosages which have given rise to various degrees of pathologic change. Two patients from the Elgin Hospital series are included, since it is known that pure radium was administered and the retention curve has been determined. It is noted that tumors require dosages in the thousands of rep; that observable pathologic changes have required a few hundred; that the natural background (including skeletal radium) varies from 7 to 30 in a lifetime (higher in isolated areas, perhaps); that large populations in high radium areas approach 5 rep in a lifetime from natural skeletal radium alone; while 1/1000 of the permissible strontium burden yields 0.2 rep in a lifetime. Exceeding this latter burden by fifty times would yield 10 rep in 70 years. This would not more than double the usual low skeletal background radiation and leave it well within the range of values; the highest backgrounds encountered in any large areas would be raised about one-third. The general belief of the Subcommittee is that this would produce no perceptible effect.

It is noted that the International Commission on Radiological Protection, using a somewhat more arbitrary procedure, has adopted a figure twice as great for the large population (one tenth of the industrial permissible level) so that there is a large measure of agreement.

Therapy by Removal of Radioelements.—This subject was not discussed by the Subcommittee, but was treated thoroughly at a meeting in October, 1955, the transactions of which will be published by Argonne National Laboratory. A summary of the present status follows:

Clinical and experimental evidence to date shows that there are two effective methods of removing radioelements from the body or prophylactically minimizing their deposition. These are the use of zirconium citrate and of chelating agents, particularly ethylenediamine tetracetic acid (EDTA). Both of these have their optimum effectiveness if given immediately after exposure. The use of the two methods in combination, at least experimentally, appears to be more effective than either one alone.

The chelating agents are mainly effective in removing radioelements from the soft tissues and causing their excretion. Under optimal conditions (that is, large doses administered early) they reduce bone deposition by a factor of two. They are effective on the transuranic elements and rare earth fission products, but for known chemical reasons they are not effective on the alkaline earths such as strontium and radium.

Zirconium citrate appears to be effective as therapy for almost all types of fission products, as is to be expected from the postulated modes of its action. It is particularly useful in minimizing bone deposition of radioelements and if given early, at least in the dog, it has been shown to remove almost all the plutonium from all the tissues.

No method has yet been developed for the removal of significant amounts of strontium. From the chemical standpoint the only promising approach to date appears to be one using agents which pick up the radio element by cation exchange, such as zirconium citrate. Other experimental approaches, particularly involving

dietary and hormone therapy with known influence on skeletal metabolism, are under investigation without clear clinical implications at present.

Treatment of individual situations will necessarily be influenced by consideration of route of entry (e. g. lung or in a wound) and the isotopes involved, bearing in mind that most of the experimental work has dealt with intravenous administration and that clinical experience to date has been severely limited.

TABLE I.—*Data on Fallout (calculated from Tsuzuki, loc. cit.)*

A. ANALYSIS OF "ASH" FROM TEST OF MARCH 1, 1954, MADE ON MARCH 26

Isotope	Half-life	Percent of total activity on March 26		Relative atomic yield	Fission yield
		Measured	As of Mar. 1		
Fission products:					*Percent*
Sr^{89}	53 d.	1.0	1.4	74	4.6
Sr^{90}–Y^{90}	27 y.	0.04	0.04	200	5
Zr^{95}–Nb^{95}	65 d.	8.0	10.5	(500)	6.4
Y^{91}	61 d.	8.0	10.8	660	5.9
$Ru^{103,106}$; $Te^{129,132}$; $I^{131,132}$	----------	15.0	?	?	13.5
Ba^{140}–La^{140}	12 d.	11.0	50	300	6.1
Ce^{141}	33 d.	7.0	12.3	410	6.0
Ce^{144}–Pr^{144}	282 d.	4.0	4.3	610	5.3
Pr^{143}	14 d.	16.0	59	830	6.0
Nd^{147}	11 d.	9.0	46	510	2.6
				(Relative to fission yield)	
Activation Products:					
S^{35}	87 d.	0.05	0.06	5.2	0.05
Ca^{45}	152 d.	0.2	0.22	34	0.3
Other:					
U^{237}	7 d.	20	260	1,820	18
Pu^{239}	24,000 y.	0.0004	0.0004	3,500	35

NOTE: After extrapolating activity back to March 1, relative yield is obtained multiplying by the half-life in days. Where 2 isotopes were measured, half of this value is taken for the parent; an intermediate value was taken for Zr^{95} since the daughter has a 35-day half-life.

B. ANALYSIS OF AUTOPSY MATERIAL 207 DAYS AFTER THE FALLOUT (FIGURES IN $\mu c \times 10^{-3}$ PER KILO WET WEIGHT)

	Liver	Kidney	Lung	Muscle	Bone
Ru and Te	----------	0.9	----------	0.2	2
Corrected for decay (as Ru^{106})	----------	1.3	----------	0.3	3
Zr and Nb	1	1	0.4	0.3	2
Corrected for decay	9	9	3.6	2.7	18
Ce and Pr	2	1	0.5	0.5	20
Corrected for decay	3.4	1.7	0.8	0.8	34
Sr	0.6	0.4	0.1	----------	1
Sr^{89} (if 97%)	9.0	6.0	1.5	----------	15
Sr^{90} (if 3%)	0.27	0.18	0.05	----------	0.45

NOTE.—This indicates that internal radiation was well within permissible limits throughout, amounting to a few mrep/day. In the event the figures for skeletal Ce and Sr were transposed in the report, the Sr^{90} burden appears to be at the permissible level.

TABLE II.—*Background and effective radiation dosages*

A. NATURAL BACKGROUND RADIATION, MREP/YEAR

	Libby	Burch and Spiers	Sievert	Other
Cosmic:				
Sea level	35	16		Lea gives 730, which is probably in error.
5,000 feet	50			
10,000 feet	100			
15,000 feet	170			
20,000 feet	375			
Earth gamma		58	94-296	Sievert gives one value of 520.
Earth, granite	110			
Earth, sedimentary	43			
Over ocean	20			
Body K^{40}	19	18.2		
Body C^{14}	1.5	1.0		
Body radium (dose to skeleton)	[1] 6.7-67			Rochester, N. Y., value 16.

[1] Extremes in Illinois.

NOTE.—This emphasizes the variability in background, even at sea level. In various localities the value might vary from 100 to 420 mr/year; the latter might be taken as the maximum which any large population receives.

B. VARIOUS LEVELS OF SKELETAL IRRADIATION (IN REP)

Patient* with sarcoma (pure radium) at 24 years	6,000
1.0 μc radium retained 24 years after dosage	2,000
Patient* with minimal skeletal changes, 24 years	800
Permissible burden (0.1 μc) sustained 24 years	100
Minimum dose of x-ray reported to induce tumor	1,500
Normal range of background radiation, external and internal, 70 years	7-30
High large-population Illinois radium level, 70 years	4.7
1/1000 permissible Sr^{90} level, 70 years	0.2

NOTE.—patients cited are known to have received pure radium injections. In other reported instances where the thorium chain may have been included in the dose, the radium dose would be calculated as low as 300 rep.

Recommendations.—The Subcommittee made the following suggestions in relation to its study:

Attention should be given to the physiological state of the animal in relation to absorption and toxicity of radioelements, particularly in the case of absorption through the usual routes (lug and gastrointestinal tract). Present information is partial and is practically limited to the alkaline earths and iodine.

Further information on the retention of alkaline earths as a function of age and species and other variables, is needed.

The relation of experimental data on life shortening to the probable picture in man needs clarification, and further verification of the apparent lengthening of life at low doses. These problems are of importance in the isotope toxicity field as well as in relation to external radiations.

The past work on distribution of various radioelements which have not received intensive study should be extended, since unusual radiochemical toxius may be expected to appear occasionally.

Account should be taken of the applicability of the power function to the retention of radioelements, since it would appear that in some cases the present intake levels are much too stringent owing to our past reliance on the half-life concept. Further critical evaluations of the RBE, particularly for alpha radiation, is very desirable for similar reasons. The RBE should be evaluated separately for the several modes of damage.

It is believed that there may be a considerable number of persons who have received radium in the past, who are alive and not seeking medical help. Any means which could be found to obtain an unbiased group of individuals would be extremely desirable, since only in this way can the degree of variability in human response be estimated. For similar reasons, any promising environmental study involving areas of different natural background should be encouraged.

All of the above personnel are members of the faculty of the University of Rochester School of Medicine and Dentistry, Rochester, New York.

PERMANENT AND DELAYED EFFECTS OF IONIZING RADIATIONS FROM EXTERNAL SOURCES

I. INTRODUCTION

While it was recognized soon after their discovery that x-rays and the radiations from radioactive materials could cause acute injury to living tissue it did not become apparent until later that they could also give rise to more subtle permanent and delayed effects which are of prime significance in considering the problem of permissible human exposure.

Laboratory studies of long term effects have been relatively few, partly because their importance was not early appreciated and partly because they are very expensive and time consuming owing to the necessity for maintaining considerable numbers of animals for all, or most, of the their normal life spans. In consequence the data on late effects in animals are meager in certain areas. Such data as there are in man are sufficiently in agreement with those on other mammals to lead to the expectation that extrapolation from lower mammals to man will be possible with fair accuracy.

It is the present purpose to review the long term biologic effects (other than genetic) of radiations from external sources, with emphasis on man, although results of animal experimentation will be drawn upon to illustrate fundamental principles and mechanisms in radiation biology.

II. PERMANENT AND DELAYED EFFECTS OF IONIZING RADIATION IN GENERAL

If animals, which have been irradiated, escape death initially they appear to recover but tend to die prematurely. It is becoming established that in mammals, shortening of life span is a general effect of whole body exposure to ionizing radiation.

There has been a tendency to seek the cause of premature death as a consequence of irradiation in increased incidence of specific disease, especially cancer. While this may be justified in the case of partial body irradiation from external sources or from locally deposited radioactive materials, it probably is not for whole body irradiation. There is evidence that at the median death time populations of irradiated animals have approximately the same incidence of the same diseases as do the controls at their median death time. This is more reasonably interpreted as indicating that irradiation produces primarily the syndrome of premature aging, with concomitant disease, rather than that it, in itself, induces all the diseases of advanced age.

The major permanent and delayed effects of total-body irradiation may be listed categorically in terms of pathologic entities as follows:

A. Increased incidence and/or severity, at given ages, of disease entities to which particular animal species or populations are susceptible. This may occur, and probably usually does, largely as a result of accelerating the time of onset of these diseases and may therefore be considered a part of the acceleration of aging produced by irradiation. It appears that the clinical history of the animals is compressed or telescoped in time in these respects. Included with these disease entities are cancers of various types to which the animals are susceptible, and possibly also cataracts which develop late in a species in a manner similar to the development of cataracts with age in that species.

B. Temporally accelerated involutional, hypoplastic or atrophic, and fibrotic changes in tissues and organs, which changes do not constitute individual disease entities but which are identical in appearance with those occurring during the "normal" course of aging. There is a high degree of correlation between the degree of temporal acceleration of this pathologic picture of accelerated aging and the size of total-body dose or daily dose rate. It should be emphasized, however, that an accurate evaluation of the degree of acceleration of involutional changes produced by certain doses can only be observed in experimental animals at times, after single doses, long after maximum regeneration and repair of the single insult has occurred, or with chronic irradiation, after irradiation has been stopped and recent acute effects on cells have repaired as much as they will.

Although differences exist among species, some of the radiation-accelerated senescent changes in tissues and organs which have been observed are:

(1) Hypoplasia or atrophy of many tissues and organs, especially the thymus, lymph nodes, splenic lymphatic tissue, bone marrow, germinal epithelium, skin, and bone growth centers. Hypoplastic changes in hemopoietic organs are reflected in lowered blood cell counts.

(2) Fibrotic changes which are fairly generalized, but which are commonly noticed in blood vessels generally, in skin where there appears to be increased collagenous tissue and decreased or degenerate elastic tissue, in and/or around lymphatic organs and endocrine organs, and in the myocardium, where focalized fibrosis occurs with age. If the small arteries of the kidney are affected sufficiently, there may develop nephrosclerosis and hypertensive disease.

(3) Pigmentary changes, including greying of hair and increases of pigments in cells of the epidermis, connective tissues, endocrine glands, myocardium and other tissues.

General physiologic changes which are usually associated with aging and which may be accelerated by irradiation include, among others: decreased muscular strength and endurance, lowered recuperative powers and tissue repair capacity and speed, lowered fertility and potency, generalized reduction of elasticity, and increased blood pressure.

Factors included in these first two categories are among those which constitute the general change which may be called "radiation-accelerated aging." The fundamental mechanisms of this change are as incompletely understood as are those of "normal" aging, except that radiations and their known effects are recognized as accelerating agents. The subsequent development of the histologic changes in both radiation-accelerated and "normal" aging appear qualitatively identical. However, it is at present sometimes difficult to distinguish between accelerated aging effects and induced pathologic effects except by arbitrary definition.

C. Induced disease entities or definitive effects, not necessarily specific for irradiation, which rarely occur spontaneously in animals of any age in the species in question, or certain effects and diseases whose know pathogeneses may differ from those occurring in the aging process but which may produce similar final results. In the latter case such effects occur earlier than the specifically comparable effects associated with accelerated aging.

Included in this category are, among other effects:

1. Nephrosclerosis and related hypertension produced essentially by the relatively direct damaging effects of radiation on cells in the kidneys, e. g. components of vessel walls, so that this disease occurs well in advance of any considerable degree of acceleration of other senescent changes. According to some data, renal hypertension once established and progressive, may increase the vascular sclerotic processes in many regions throughout the body and these changes are sometimes associated also with progressive hypoplasia or atrophy of organs in which the vessels become fibrotic.

2. Cataract formation which occurs well in advance of the generalized aging processes if the radiation dose to the lens has been sufficiently high to damage or destroy cells of the anterior epithelium and/or depolymerize the cement substance between fibers. There are two general histologic types of radiation cataract, the purely vacuolar type, which is reversible, and the granular type which is irreversible. The senile cataract, although similar in the ultimate effect to radiation cataracts, is generally more progressive, occurs usually when other aging changes are considerable, and may have a different pathogenesis.

3. Decreased fertility resulting from direct damaging actions of radiation on gametogenic cells and gametes. The mechanisms by which direct actions of radiations decrease fertility are quite different and more numerous, as far as we know, compared with those involved in decrease of fertility due to aging or accelerated aging.

In senescence of the testis, as in testicular damage resulting from infectious and cachectic diseases and physical and chemical damaging agents, the spermatozoa and more mature spermatogenic elements are affected first and most markedly in the seminiferous epithelium, and decreased fertility, if potency is retained, is due to lack of production of sufficient numbers of spermatozoa. In the case of the senescent ovary, there is depletion and/or failure of development of follicles, which is associated with a complicated endocrine disturbance.

Irradiation effects on the gametogenic cells and gametes themselves may decrease fertility in more than one way, prior to and in addition to, the effects involved in acceleration of aging, and these mechanisms, other than those genetic and relating to the fertility of future populations, are as follows:

(a) by reducing the number of gametes produced through effects on primitive radiosensitive precursors of the gametes. This reduction may be partial or complete, or temporary with partial or complete recovery, or permanently complete, depending upon dose. The number of gametes produced may be reduced also indirectly by other diseases which irradiation causes or accelerates.

(b) by damaging in various ways the gametes produced so that they are incapable of fertilization.

(c) by damaging chromosomes of gametes in such ways that they are capable of fertilization but produce zygotes which are incapable of complete and normal development to full-term viable foetuses and die *in utero*. The results of such effects constitute the condition known as "semisterility," which is genetically transmissible to viable offspring.

4. Increase in incidence of other non-neoplastic diseases not common to the species even during the senescent period. There are not sufficient conclusive data in this area of the problem to warrant discussion, but it would appear worthwhile to indicate that research is needed in this aspect of the study of long-term effects of irradiation.

5. Induction of neoplasms rarely, if ever, occurring spontaneously in a species, but caused by the destructive actions of radiation on specific tissues with the initial establishment of precancerous states. It is possible that the later influences which cause the development of neoplasia from these precancerous states may be brought about by the same mechanisms which cause the development or accelerated development of the neoplasms which are of common occurrence in the species with advancing age.

III. PERMANENT AND DELAYED EFFECTS OF IONIZING RADIATION IN PARTICULAR

A. The Shortening of Life Span by Ionizing Radiation

Since there is some evidence that radiation effects depend upon the age of the animal at the time of exposure, some consideration will be given first to the lethal dose as a function of age.

1. *Lethal Dose as a Function of Age.*—The average of median acute lethal dose, LD_{50}–30 days, for young adult mammals is similar for those species which have been studied and lies within or near the range 600 ± 300 roentgens. While it is customary to refer to LD_{50} of a given strain as if it were a specific property, independent of age, this is not justifiable.

In the mouse the susceptibility is maximal at 30 days then decreases rapidly to that seen in young adults. In the rat, which has been studied more extensively, the LD_{50} at three months of age is about double that at three weeks. Beyond three months it diminishes with age and there is some indication that, for the adult animal, the LD_{50} decreases about as the life expectancy. More study of this relation is required to make it wholly quantitative, but it is evident, now, that the susceptibiliy of a whole population is not describable by a single LD_{50}. The published values are usually obtained from the young adult and are therefore maximal or nearly maximal for the strain. In attempts to estimate LD_{50} in man this age dependence should be taken into consideration.

2. *Life Shortening by Single Doses.*—Existing data on rodents subjected to single whole-body doses of radiation are compatible with the view that life is shortened in proportion to the dose for doses less than about two-thirds of LD_{50}. In this range life shortening is about 25% of the adult span per LD_{50}. With greater doses this effect increases more rapidly, attaining about 50% for survivors of LD_{50}. No similar data are available for longer-lived mammals, or for man, but it may be possible eventually to obtain some estimate of the effects of single doses in man from the Japanese survivors.

There are a few data from the rat indicating that shortening of life for a given single dose is about the same, independently of the age at which it is administered to the adult animal, providing the animal is destined to live long enough to make the shortening wholly manifest.

Owing to the difficulty of detecting small changes with limited numbers of animals it cannot be assumed with confidence that life-shortening is proportional to dose down to small doses at the rate given above. Actually there is reason to suppose that the effect of small doses is less than that indicated by the present data. This point will be discussed in considering the effects of chronic irradiation.

3. *Life Shortening by Multiple Doses or Chronic Irradiation.*—Small laboratory animals subjected to irradiation either at high daily rates for short periods or low daily rates for long periods suffer about 7% life shortening per LD_{50} and the effect is proportional to dose, or nearly so, for doses up to about three times LD_{50}. The data for low daily rates and small total doses in the 100 r range are not definitive, there being almost as many showing prolongation, as shortening, of life. While this again is probably due to failure to use sufficient numbers

of animals to measure small effects, it leaves to be resolved the possibility that low daily doses actually prolong life, unlikely as this may seem.

No satisfactory explanation has been offered for the greater shortening of life from single doses than from divided doses of the same total magnitude. Nevertheless the difference appears to be well established for large single doses. However, because divided doses, at rates at least as high as 120 r per day, cause the same effect per accumulated roentgen as divided doses at quite low daily rates, it is difficult to understand why a single dose of 120 r would not act the same. Possibly it does and the apparent disagreement is owing to inaccuracy of single dose data for doses in the 100 r range and below.

4. *The Concept of Irreversible Injury.*—To account for shortening of life as an after effect of irradiation it may be supposed that radiation injury is in part reversible and in part irreversible and that the irreversible component is equivalent to premature aging in the sense that it ultimately deprives the animal of part of its expected life span. This view of irreversible injury does not prescribe whether it is equivalent to abrupt aging at the time of injury or consists in the initiation of aging processes which gradually develop. It is interesting that limited observations in the rat indicate that irreversible injury is measurable, after an interval of presumed complete repair, as a reduction in acute lethal dose. This suggests that aging or its counterpart is laid down at least partially at the time of injury and is potentially observable as some form of persisting lesion, but as yet this phenomenon has not been related to histopathologic changes to be discussed below.

5. *The Effect of Chronic Irradiation in Man.*—The deaths of 82,441 physicians reported in the Journal of the American Medical Association from January 1, 1930, until December 31, 1954, were reviewed by Shields Warren.[1] In physicians grouped according to possible radiation exposure the average age of death was as follows:

	Years
No known contact with radiation	65.7
Some exposure (dermatologists, gastroenterologists, tuberculosis specialists, urologists)	63.3
Radiologists	60.5
U. S. population over 20 years of age	67.1

In comparison with non-exposed physicians the shortening of life of radiologists is 5.2 years or 11% of the adult life span (after 20 years). If extrapolation from the animal data, reviewed above, is permissible, this would be expected to result from chronic whole body exposure to about 1.5 LD_{50} dose or possibly 1000 roentgens. Although this exposure was partial body and possibly less effective, it seems unlikely that the equivalent whole body exposure differed from the above value by a factor greater than 2 or 3. Consequently it appears that, within these limits at least, extrapolation from short-lived animals to man may be made with some confidence on the basis of percent life-shortening per unit dose.

B. Acceleration of Aging by Irradiation

There are no definitive data on the effects of total body irradiation on the aging processes *per se* of man. Perhaps some information on this effect in man will be forthcoming in time as a result of observations which may be made on survivors of the atomic bombing in Hiroshima and Nagasaki. The delays effects which have been observed in these Japanese are reported subsequently under other headings.

In view of the relation between the degree of acceleration of aging observed histologically in experimental animals and the size of the total body dose which the animals received, and in view of the probability that populations of irradiated animals lying prematurely die essentially as the result of premature aging and associated diseases, it seems reasonable to expect that a direct relation may exist in irradiated populations between the amount of life shortening caused by irradiation and the degree to which irradiation has accelerated aging, and that any total-body dose of external radiation which has caused shortening of life in a population of animals has caused a proportional acceleration of aging.

Some of the localized tissue effects produced by partial body irradiation in humans are histologically similar to changes occuring in the syndrome of premature aging. However, many of these changes, some of which are mentioned

[1] Before the Radiation Research Society, May 19, 1956, Chicago, Illinois.

below, are effects induced directly rather than phenomena of accelerated aging.

In the human skin single loses of 500 r to 700 r of x-rays may produce permanent epilation. Somewhat smaller doses causing temporary epilation may cause decreased pigmentation or greying of hair which returns in the irradiated areas. These doses in the erythema dose range or somewhat higher may also cause increased pigmentation of the skin in the irradiated regions, some degree of epidermal atrophy, and some decrease in sebaceous and sweat glands. Hyperkeratotic areas of skin, vascular sclerosis, and dermatitis may also be late sequelae of irradiation of skin. Surface doses of about 1600 r more or less may produce considerable permanent dilatation of capillaries (telangiectasia) in the area irradiated.

Changes in skin are also late effects of chronic irradiation and are seen commonly in the skin of the hands of persons working with radiations. Roentgen dermatitis and the roentgen ulcers which often develop from this condition are considered precancerous conditions because of the frequent development of malignancy in such regions.

Renal hypertension may be produced in man within periods from several months to several years by single localized doses of x-rays of about 3000 to 5000 r or by chronic irradiation, e. g. by a total dose of 2300 r in 35 daily doses to the abdomen, but there are no definitive dose-effect on the late incidence of kidney disease and arteriosclerosis related to generalized radiation acceleration of aging in man. In rats, nephrosclerosis, with renal hypertension, and generalized arteriosclerosis are characteristic delayed effects associated with accelerated aging changes late in their lives following single total-body doses of 500 and 600 r or greater. Much larger doses localized to the kidney are required to cause these renal changes and associated effects to appear early in the life of irradiated animals.

Irradiation of parts of the brain of man with total doses of about 5000 r or more given as a single dose or within 2 or 3 weeks in fairly large fractions may cause progressive sclerosis of blood vessels with subsequent secondary degeneration of brain tissue and sometimes rupture of blood vessels and hemorrhage from one to several years after exposure.

Hypoplastic and atrophic changes, often associated with arterial sclerosis, have been observed in human hemopoietic organs long after localized irradiation. Permanent effects have also been observed in bone heavily irradiated, and in the length of bones irradiated heavily over their epiphyseal ends during the growth period.

The fragmentary data on delayed effects of localized irradiation in human tissues which are similar qualitatively to changes which are associated with aging, are difficult to interpret in terms of accelerated aging, especially since many of the human cases from which the data are obtained suffered from malignancy or other serious disease processes.

C. Late Hematologic Effects of Irradiation

Data collected during the period after World War II may be summarized very briefly as follows:

With respect to occupational or daily exposures over periods of months or years, doses in the range of 0.5 r/day have been reported effective in producing slight depression of the number of circulating lymphocytes and total leukocytes in the peripheral blood of man. A 77 week period of exposure to doses averaging 0.2 r/week effected a decrease in the number of leukocytes in another group of workers. One authority has found some statistical evidence indicating that doses as low as 0.5 r/year may depress the lymphocyte count very slightly. These and similar findings (which are considered in more detail and tabulated in the review cited at the end of this paper) are not unequivocal, of course, and do not indicate with certainty that injury has occurred to the personnel in question, but they indicate in a general way, the presently accepted estimates of the "lowest effective dose."

Slightly larger exposures, for example a total X-ray dose of 40 r given in increments of 15–20 r, or a total dose of 200–300 r received as a series of daily 5–10 r exposures, caused depression of the peripheral blood lymphocyte level in man, the larger cumulative dose being associated with decreased numbers of all types of white blood cells.

Survivors (924) of the Hiroshima atomic bombing, receiving doses estimated at 400 r total-body, and all showing epilation, revealed relative lymphopenia 2 years after exposure. There was greater than normal variability in the blood picture of this group. Four of 5,075 survivors exposed at less than 1,500 meters in the

Nagasaki bombing revealed, after latent periods of 4 to 7 years, refractory (fatal) anemia, with associated leukopenia and thrombocytopenia.

A statistical analysis in 1954 of the hematologic data obtained by the Atomic Bomb Casualty Commission on Hiroshima survivors 5 to 8 years after the bombing indicated that there was no increase in leukopenia, leukocytosis, or anemia in the exposed as compared to the control population. Up to 1953 no cases of aplastic anemia had been found in the survivors in Hiroshima.

Observable changes in the structure of leukocytes (in contrast to the changes in numbers described above) appear to offer considerable promise as sensitive biological indicators of radiation exposure.

Two of the most sensitive morphologic indicators of radiation effect on blood are increased numbers of refractile neutral red bodies in lymphocytes (observed in humans receiving .05 r per day) and an increased incidence of lymphocytes with bilobed nuclei in peripheral blood, which has been observed in a considerable number of cyclotron workers after they had worked about 3½ months during which they received exposures which did not exceed the M. P. E. The incidence of the abnormal lymphocytes returned to normal after extra shielding was installed.

Although there is much conflicting information and opinion relative to late hematologic effects of exposure to ionizing radiation, a review of the available data leads to the formation of certain fairly clear impressions if not definite conclusions.

Early radiologists and radiation workers developed blood pictures characterized by moderate lymphocytosis and leukopenia. These changes were often sufficiently definite to be recognized on an individual basis, as well as by statistical analysis of grouped data. They have been interpreted in various ways, of which the most likely seems to be as follows: initial injury causes a depression of lymphopoiesis, which is followed by a recovery phase characterized by a compensatory increase in activity. During chronic exposure lymphopoiesis presumably "escapes" from the depressing effect and enters the compensatory hypertrophy state. Most of the early workers had exposures which would undoubtedly greatly exceed present maximum permissible doses.

Studies made during the more recent period reveal that the most characteristic changes following chronic exposures in or below the maximum permissible dose range are slight lymphopenia and morphologic alteration of the leukocytes, particularly lymphocytes. The absence of lymphocytosis might be explained by the fact that even chronic exposures are much more intermittent now than earlier. Furthermore, since both injury and the compensatory hypertrophy are, within limits, proportional to the magnitude of exposure, it is possible that present chronic exposures are too slight, as well as too intermittent, to produce adequate stimulus for "escape" into the compensatory hypertrophic phase.

In any event, morphologic changes are probably the most sensitive indication of radiation injury. This is not surprising, for one might expect to find larger numbers of young cells being released into the blood stream following transient bursts of increased leukocytopoiesis. Furthermore, when parent cells have been injured by radiation, abnormalities of mitosis (with the production of abnormal daughter cells) would be expected to occur more frequently than normally. Hence abnormal as well as early cells should appear in the peripheral blood in increased numbers.

The relationship of this type of change to the incidence of leukemia and other latent effects of exposure is very poorly understood, and it is highly desirable that more information be obtained. The compilation of data representing sensitive hematologic indices of radiation exposure in large groups of radiation workers should be vigorously pursued so that eventually there may be enough long-term studies of the health of the workers to permit adequate evaluation of the significance of the more sensitive radiation-induced biologic changes. Should such changes prove to be truly premonitory of an increased incidence of latent effects, it would be important to adapt biologic monitoring procedures accordingly.

One of the greatest hindrances to the present interpretation of highly sensitive hematologic and presumably other biologic changes is the absence of adequate physical monitoring data for exposures below the maximum permissible dose range, so that evaluation of exposures of individual radiation workers is grossly inadequate for the interpretation of hematologic data of the type under discussion. It is important that in selected situations, individual physical monitoring be instituted which is in the same range of sensitivity, with regard to quantitative interpretation, as the biologic monitoring.

D. Carcinogenesis by Radiation from External Sources

This section deals primarily with malignant disease in human populations exposed to ionizing radiation.

It has been clearly established that malignant disease may arise in tissues heavily irradiated by ionizing radiation. Animal experimentation and experience with irradiated human subjects show that almost any tissue can become neoplastic under the proper conditions of exposure. This report does not treat of the type of radiation-induced malignancy which is usually the result of intense, repeated exposure of a small portion of the body, but will consider only malignant disease in populations in which the entire body or at least a large portion of the body of human subjects has been exposed to acute or chronic doses of ionizing radiation from external sources.

Leukemia is commonly associated with exposure of the body to radiation. The close association between exposure and the disease has been described under three different conditions of exposure. The first is that noted in the radiologists who have been chronically exposed. It should be pointed out that the actual number of cases of leukemia is not great even though the incidence is much higher than that noted in the general male population and in other physicians. March, in a review, was able to find only 37 published cases. Furth and Lorenz state that one reason for such a low incidence of leukemia in these persons who were probably heavily exposed in the early days of x-ray technology is that their exposure was partial body rather than total-body. The average age of the 14 radiologists dying of leukemia from 1928–1949 as 58.8 years.

The increased incidence of leukemia in the Japanese exposed to the nuclear explosion in Hiroshima and Nagasaki is the only example of this disease occurring after a single acute exposure of the entire body to ionizing radiation. In this case there is a good correlation between the diseases and the dose. Even in the highest exposure group, however, the incidence is still small (1.25%). Most of the cases are of the myeloid type. However, lymphoid leukemia is known to be comparatively rare in Japan.

There are two examples which illustrate the increased incidence of leukemia under the third condition, i. e., that observed in persons given therapeutic treatment with x-rays to a large portion of their body. One is found in persons with ankylosing spondylitis who have received intensive treatment with x-rays to the entire length of their spine. A total dose of 2,000 r was not unusual in a treatment series and such series were often repeated. There is a good correlation between the incidence of leukemia and the number of treatment courses. The second example is found in children given one or more treatments to their chests in infancy for enlargement of their thymus glands. In one study of children receiving 100 to 1500 r in 1 to 3 treatments to the chest, 7 of 1,722 treated children developed leukemia. This incidence was ten times that expected for children in the state in which the study was done. There were no cases of leukemia in 1,795 untreated siblings at the time of the study. There were 3 cases of leukemia among 604 children receiving less than 200 r, and 4 cases among 804 children receiving more than 200 r. The children in this study showed leukemia incidence of about 0.4%, but they may represent a special situation since the treatment was given when they were very young and since there is no apparent correlation with the x-ray dose.

Aside from leukemia, the only studies on malignant disease in persons exposed to radiation from external sources are found in statistical surveys by Dublin and Spiegelman and by Warren of the cause of death in radiologists and other physicians. Dublin and Spiegelman find that the incidence of malignant disease is lower in physicians than in the general male population of comparable age. It is slightly higher in radiologists but, apparently, not significantly different from that in other specialists or non-specialists who presumably have not received the same exposure to radiation. Interesting is the observation that the highest cancer incidence, twice that in the total group, is found in psychiatrists and neurologists. The data of Shields Warren on a much larger series of physicians show a somewhat higher percentage of cancer deaths in radiologists than in other physicians.

In consideration of animal experiments, uncertainty exists as to whether or not there is a true dose threshold for the production of malignant tumors by irradiation. The answering of this question would require an extremely expensive, massive experimental program employing very large numbers of animals and much time. Experimentation of this kind with low doses is further complicated by the occurrence of spontaneous malignancies to which various

species of animals are susceptible, and also by the variability in response of equally exposed animals. If the fundamental cause, or one of the indispensable factors, in radiation carcinogenesis is the induction of somatic mutations, it would appear possible that radiation carcinogenesis, or perhaps the induction of precancerous states by irradiation, has no dose threshold. However, this reasoning may be applied to other disease states and accelerated aging as well.

In any event the incidence of cancer in exposed populations is not sufficiently great to be regarded as an important contribution to the degree of premature death occurring in a group such as that of the American physicians discussed above.

E. Radiation Cataracts

In this section emphasis is placed upon the effects of the radiations from nuclear disintegrations and high energy particle accelerators on the development of ocular, especially lenticular, lesions in humans. This in no sense deprecates the excellent work done with other animals in which the pathologic development, biochemical changes, and dose-time relationships of lenticular abnormalities have been elucidated. The present reservoir of several thousand persons who have been exposed to the radiations from atomic weapons, and the few hundred humans exposed to the beams of particle generators during the last ten to fifteen years makes it apparent that a reasonably accurate evaluation of the magnitude of the problem of radiation-induction of cataracts in humans can be made from the information currently available.

There are no quantitative or definitive dose-effect data from humans or animals in regard to increased incidence of cataracts late in life as a result of radiation acceleration of aging processes. It is hoped that long-term observation of persons exposed to radiation and of animals in life-span experiments will provide such information.

It is not surprising that a great variety of possible causes of cataracts have been discovered. Histologically the lens is such a simple structure that its possible ultimate response to injury is limited almost exclusively to cataract formation. Considering only idiopathic forms of the disease and excluding those cataracts resulting from injury, including radiation injury, metabolic disease, congenital defects, etc., one is left with a phenomenon definitely related to increasing age.

Despite much effort it is still not yet clear just how the senescent process causes this local change. However, there are differences histologically in the development of this change as compared with the development of radiation-induced cataract. In the aging process the lens grows continuously throughout life but the growth rate becomes slower with advancing age, never reaching zero until the tissue dies in cataract formation. Radiation-induced cataract is the result of direct destructive actions of radiation on the anterior epithelium and possibly on the cement substance between fibers.

It is interesting to note that before it was recognized that radiation cataracts were appearing in cyclotron workers, Evans reported in 1948 that cataract production in mice by fast neutrons relative to x-rays increased significantly with chronic exposure. Young animals exposed during the pre-natal or early post-natal period show markedly greater lenticular radiosensitivity than do older animals.

By December 1948 it was known that at least five nuclear physicists of mean age 31 had incipient cataracts. In January 1949, eleven physicists were examined and ten were found to have cataracts, in three cases severe with definitely impaired vision, in four cases moderate, and in three cases minimal. They were estimated to have received, over periods of 10 to 250 weeks, a median dose of fast neutrons of 50 *n*, while the range of doses was 10 *n* to 135 *n*. At the time the cataractogenic exposures were being received, most of the men were given periodic blood counts, which revealed no change in blood picture warning of overexposure to radiation.

In adult humans exposure to x-rays in excess of about 2000 r has been thought necessary to produce cataracts.

Fillmore, in a survey of the Hiroshima Japanese survivors, based in part upon studies by Kimura in 1949, about 5 years after the detonations, reported 98 cases of cataracts, eighty-five of which were among the 922 survivors 1000 meters or less from the hypocenter. In 1955 Sinskey reported the results of an intensive investigation of 8700 exposed and nonexposed individuals made between May 1951 and December 1953, six to eight years after exposure. There were 154 survivors with posterior subcapsular polychromatic plaques large

enough to be visible with the ophthalmoscope. These radiation-induced pathologic changes in the lens did not in general impair vision significantly when examined, and in most cases were correctable with proper lenses to provide normal vision. Of this group only 25 individuals had vision less than 20/25.

According to Sinskey's study, the human lens is quite sensitive to nuclear radiation in doses which produce epilation and other acute effects but are insignificant with respect to impairment of vision.

Of the approximately 8000 exposed survivors of Hiroshima and Nagasaki who have been examined during the last decade there have been found 10 cases of severe cataract, approximately 25 cases of slightly impaired vision due to posterior polychromatic plaques and perhaps two hundred cases with minimal pathologic lenticular lesions detectable by competent slit lamp examination.

It may be concluded that the atomic bomb explosions over Japan have resulted in negligible loss of vision to date.

F. Effects of Ionizing Radiation on Gametogenesis and Fertility

1. *The Male.*—Spermatogonia are the most radiosensitive cells of the seminiferous epithelium and one of the most sensitive of the body with respect to inhibition of division and with respect to the destructive actions of radiation. Apparently both inhibition of mitosis and destruction of spermatogonia, and differentiation of these cells following irradiation contribute to their disappearance from the seminiferous tubules, the relative contribution of each mechanism varying quantitatively according to size and mode of administration of dose.

The delay in the beginning of regeneration of these cells after irradiation is dependent to a considerable extent upon the dose. Following reduction or depletion of spermatogonia the later germ cell generations undergo maturation-depletion and disappear in the order in which they are formed until a point of maximum hypoplasia is reached. The destruction of some of the cells of more mature generations by relatively high doses may hasten this process. Spermatocytes, spermatids, and spermatozoa are of increasing radioresistance in the order given. The time for the development of maximum hypoplasia of the seminiferous epithelium is about 3 or 4 weeks, sometimes longer, depending upon dose and species, and this time is close to that required for the development of a spermatozoon from a spermatogonium.

Histological sterility, by definition a lack of spermatogenic elements and sperm, may be temporary or permanent and the two often appear very similar upon casual histologic examination. The time factor is of great importance in the prognosis as regards sterility.

For relatively low doses and for certain laboratory animals whose germinal recovery capacity is relatively large, regeneration, if it is to occur, begins before the height of depopulation of germinal epithelium is reached or soon thereafter. With certain higher doses given to such animals, a delay of beginning of regeneration for about 10 months is considered by some to be indicative of permanent sterilization. Actually, in much of the work employing large single doses of radiation the animals were not studied for the maximum time possible or desirable.

It is probable that the critical interval of time for beginning of regeneration varies among species and that for some of the larger animals, including man, whose powers of germinal regeneration are comparatively low, active regeneration may be delayed following severe radiation effects much longer than 10 months. Whether permanency of sterilization or length of the temporary sterile period is due to effects on cells involved directly in spermatogenesis or rather indirectly to effects on supporting tissues is not clear.

The testicular effects of irradiation are qualitatively similar in all mammals studied, including man, but vary quantatively according to differences in testicular radiosensitivity and recovery capacities among species. Whether a dose of radiation sterilizes permanently or temporarily depends at least as much on the natural capacity for regeneration of primitive spermatogenic cells as on the radiosensitivity of the spermatogenic cells existing at the time of irradiation.

Sertoli cells and interstitial (endocrine) cells are relatively radioresistant. Male mammals may be sterilized permanently without prominent histologic changes in the interstitial cells and without decrease in sexual potency or libido.

Following single doses of irradiation and preceding the sterile or subfertile period produced there is a period of fertility, the length of which is much less dependent on low doses than on doses high enough to affect the fertilizing capacity of mature sperm. Lower doses are required to destroy the fertilizing

capacity of sperm than are necessary to affect the viability or motility of sperm present at the time of irradiation and therefore during the initial fertile period.

This first period of continued fertility is due largely to sperm mature at the time of irradiation and possibly to some sperm in the spermatid stage or even a few in the spermatocyte stage, depending upon the dose and the length of the fertile period. The subsequent period of infertility or sterility is due to decreased numbers of sperm produced, and the fertile period following the period of sterility, if recovery occurs, is due to sperm that were developed from cells which were in the spermatognoial stage or were primordial undifferentiated cells at the time of irradiation.

In the initial fertile period litter size is subject to reduction with sufficient dose and the amount of reduction is dependent upon the dose. Litter size in the fertile period after the sterile period is usually normal or perhaps slightly less than normal. Reduction in litter size is explained on the basis of induction in sperm, and perhaps to some extent in precursors of sperm, of chromosomal aberrations which do not interfere with fertilization but which cause death of the zygote or embryo *in utero.* In terms of human considerations the equivalent result would be manifest in the form of increased incidence of spontaneous abortion following death of embryos or foetuses *in utero.*

This reduction in litter size caused by irradiation is called "semisterility", and the condition is transmissible genetically to viable offspring. Chronic irradiation at low daily dose rates appears to be much less effective in the production of semisterility, according to existing data. This may be explained on the basis that low doses are delivered to sperm populations which are continually renewed in the genitalia, and that relatively fewer sperm are subject to doses large enough to induce the chromosomal defects involved in semisterility. The lesser reduction in litter size during the second fertile period after irradiation with large single doses suggests that similar chromosomal defects in primitive spermatogenic cells or primordial undifferentiated cells are either not as significant in terms of the production of semisterility or are largely eliminated in some manner. More long-term investigations of this problem in chronic radiation experiments seems desirable to verify the degree to which regenerated sperm populations are defective in terms of semisterility.

The so-called sterile period may be a period of complete sterility or a period of subfertility or of fertility with reduced spermatogenesis, as manifest by partial atrophy of seminiferous epithelium and partially reduced sperm counts. Since critical or minimal numbers of normal potentially effective sperm per ejaculate are necessary for consistent successful reproduction, practical sterility or infertility may be associated with considerable but subnormal degrees of spermatogenesis. When spermatogenesis is partially arrested the number of sperm produced decreases and the percentages of sperm motile, alive, and normal tend to decrease also. With chronic irradiation spermatogenesis may stabilize at reduced levels for long periods of time if complete arrest does not occur, and further depressions may be slow in occurrence. Reduced sperm count and decreased quality of sperm persist accordingly.

The effects of irradiation on seminiferous epithelium are direct in that irradiation of the body with testes shielded does not produce them.

The effects of x-rays, gamma rays, and neutrons on spermatogenesis and reproduction are qualitatively similar, but neutrons are more potent in their effects on spermatogenesis and five or six times as potent in reducing litter size in matings done during the initial fertile period.

In regard to the efficiency of fractionated versus undivided doses of the same total size in producing testicular effects, there are experimental reports indicating no difference, others indicating less effect with fractionation, and others showing greater effects with fractionation.

Protraction of the dose fraction has little influence apparently on testicular effects unless the protraction is extreme, in which case the effect of a given total dose may be decreased, probably by virtue of permitting biologic recovery processes to operate at a more favourable rate with respect to the rate of production of injury by radiation.

The effects of fractionation of dose on the testes depends upon the size of the dose fraction, the interval of time between fractions, and the total dose. In general, fractionation has less influence on the effect of small total doses than on the effect of large total doses. Fractionation of large doses appears to increase damage in the mechanisms responsible for regeneration of germinal epithelium.

The dose-effect relationships in different species often appear contradictory, but are probably in reality complementary. For each species there is probably a

different dose-time relationship, in irradiation with divided doses, which is optimum for the efficient production of radiation injury. The empirical work which has been done on the testis has already made this apparent. Theoretically, in a tissue in which stem cells are radiosensitive and have the capacity both for active division and for differentiation, the most efficient mode of administration of radiation (per roentgen) to produce sterility in animals of a given species would be that designed, with respect to dose-time relationships, to take advantage of the biologic actions and reactions of the cells themselves. One of the most efficient dose-time relationships in spaced irradiation of the germinal epithelium would be one in which the dose fraction was small enough to permit attempts at division in spermatogonia but large enough to injure many of these cells to the extent that they die when mitosis is attempted, and one in which the time interval between exposures is such that the following exposure is administered when the effect of the previous dose is diminishing. A change of this inter-dose time interval in either direction would decrease the efficiency of the irradiation with respect to utilization of mitotic-linked death of spermatogonia.

In the case of cells having the capacity both for division and differentiation, irradiation tends to diminish the number of resting cells and dividing cells and by inhibition of division to increase the number of differentiating cells. It may be possible to increase to a maximum this effect in spermatogonia by suitable arrangement of the dose-time relationship in chronic irradiation. If the dose-time relationship optimum for maximum differentiation effects was quite different from that optimum for maximum mitotic-linked death, an optium compromised might be found, or these biologic effects could be handled separately with greater efficiency than is now the case.

There has been little investigation of the effects of irradiation on gametogenesis and reproduction in mammals, except for the work on rodents and some recent work on dogs. The single doses to the testes required to cause complete or nearly complete atrophy of the seminiferous epithelium are similar in size in these small animals and in the dog and man as well, all of the doses being within the LD_{50} range. However, the regenerative capacity of the seminiferous epithelium of the small laboratory animals is so great that very large single or divided doses, well above total-body LD_{100} doses, are required to sterilize permanently most or all of the animals of a group.

It would appear from data at hand that the dog, of all of the animals investigated in these respects, is the animal most similar to the human in terms of radiosensitivity and regenerative capacity of seminiferous epithelium. In general both dog and man reveal similar sensitivity which is greater than that in other experimental animals. In both cases, however, there is only little and fragmentary information on the effects of irradiation on spermatogenesis and reproduction, the minimal single or chronic permanent sterilization dose has not been studied definitively, and there is only little known of the regenerative capacity following irradiation.

The following table summarizes careful observations on male beagle dogs subjected to chronic exposure to x-rays from a 1,000 kvp x-ray machine and, in some cases, to neutrons from a cyclotron, 5 or 6 days per week.

Dose/week	Approximate total dose	Duration of exposure	Observations
0.3 r	62 r	4 yr	No significant change in sperm count.
0.6 r	124 r	4 yr	Do.
0.6 r	62 r	2 yr	Little change in germinal epithelium.
0.6 *n*	31 *n*	1 yr	Do.
3.0 r	156 r	1 yr	80 percent sterile; 20 percent reduced sperm counts.
3.0 r	312 r	2 yr	Substantial atrophy of germinal epithelium.
6.0 r	312 r	1 yr	Aspermic.
6.0 r	624 r	2 yr	Marked atrophy of germinal epithelium.
10.2 *n*	398 to 561 *n*	39 to 55 wks	Extreme atrophy of germinal epithelium.
15.4 r	477 r	31 wks	Aspermic after 375 r; sterile 1.25 years postirradiation so far.
15.4 r	634 r	41 wks	Aspermic after 375 r; sterile 1 year postirradiation so far.

Although cases of testicular atrophy in humans following irradiation have been observed since 1904, and were commonly observed soon after the Hiroshima and Nagaski bombings, little is known at present of the ultimate fate of the lesions produced in survivors and the effects of these lesions on fertility.

Regeneration of testes rendered atrophic by various doses and modes of irradiation has not been studied definitively in man. There are, however, isolated cases which have been studied to some extent, and there are reports of a zoospermia or oligonecrospermia or sterility in radiologists. Most of these cases were not studied carefully and extensively and in very few instances are there any reports or accurate estimates of doses involved. However, on the basis of the rather meager data available, certain estimates may be hazarded.

A single x-ray dose of 500 to 600 r is thought to produce permanent sterility for the human male and a dose of 250 r is thought to produce sterility for about one to two years.

If it is permissible at all to compare the meager human data with the results of many animal experiments in which regeneration was studied, the much more delayed and lower rate of testicular regeneration in man is apparent. Marked depletion of germinal epithelium is produced in the small experimental animals by doses in the LD_{50} range, but regeneration of the seminiferous epithelium is complete or nearly so in a matter of 3 to 5 months.

Man as well as the dog may have fewer of the radioresistant primordial cells, precursors of spermatogonia, or these cells may have less potential than is the case in the smaller or lower mammals. Other possible reasons for the delayed and slow recovery may be intimately associated with differences in metabolic rate and normal differences in rates of spermatogenesis. Factors which determine the relatively late maturation of the normal human testis may also modify the rate of regeneration of the human testis.

2. *The Female.*—Irradiation of the mammalian ovary can cause profound atrophy of the organ with temporary or permanent sterility depending upon the dose. Changes in the ovaries may be followed by dependent atrophic changes in accessory genitalia in most mammals.

The ova and follicular cells are the most radiosensitive cells in the mammalian ovary and cells of the corpora lutea and interstitial cells are relatively radioresistant. The radiosensitivity of the ova and folicular cells varies with their functional states at the time of irradiation. There are also marked differences in radiosensitivity between species. In most laboratory mammals the developing and mature follicles and ova appear to be more radiosensitive than the primordial follicles and ovocytes and some primary follicles persist after fairly large doses of radiation and may begin to develop long after irradiation.

Irradiation may sterilize the ovary by preventing the development of primary follicles of the ovary and by destroying the ova and follicular cells. Histologically, permanent ovarian sterility is indicated by the lack of ovarian follicles.

A dose of radiation which destroys all developing follicles causes failure of development of corpora lutea, which may lead to decrease of interstitial gland cells in animals which have these glands, since new cells will fail to be developed from corpora lutea.

Care should be used in the extrapolation of data from the mouse to human problems in regard to the ovary. The mouse ovary is peculiar in many respects. In it the primary follicles and ovocytes are exceptionally radiosensitive as compared with developing and mature follicles. The mouse ovary also has the tendency to develop invaginated tubular downgrowths of germinal epithelium and ovarian tumors, and these changes are easily accelerated and increased by relatively low doses of radiation. The peculiar differences in the mouse ovary, or the underlying causative mechanisms, are probably responsible for the exceptional radiosensitivity and the irreversibility of the effects of relatively low doses of radiation on the mouse ovary, as compared with ovaries of other laboratory mammals and the human female. In the female mouse a single x-ray dose of 150 r results in permanent sterility.

The size of the litter produced in the initial fertile period after irradiation of female animals is reduced and the size of the litter from irradiated females declines more rapidly with rising dose than the size of the litters from irradiated male mice.

Total body irradiation appears to produce greater effects on the ovary and on fertility in female animals than irradiation of ovaries alone with equivalent doses.

Since sterilization of the human ovary is a radiotherapeutic practice under certain circumstances, considerable data have accumulated on the radiosensitivity of this organ.

Single doses to the ovaries of 125 to 150 r may produce amenorrhea in 50% of women. A single dose of 170 r can produce temporary sterility for a period of 12 to 36 months. A dose of 500 r produces permanent sterility in most women,

but young women may require a larger dose. Doses between 500 r and 624 r have produced permanent sterility in 94% of a group of women (34 of 36 patients), and a localized dose of 625 r has produced permanent castration in a whole group of 72 patients.

3. *Sterility Doses for Men and Women.*—It seems quite possible that the single doses necessary to cause permanent sterility in 100% of men and women may not be far apart. However, there is insufficient information on men to permit an intelligent guess as to the exact amount of the difference.

It would appear that both male and female humans are probably among the most radiosensitive of those mammals studied, with respect to gonadal effects of irradition. It is also probable that the differences between single temporarily sterilizing doses and single permanently sterilizing doses of radiation are relatively small in the case of humans as compared with most of the laboratory mammals studied. On the basis of the data available the single gonadal dose of x- and gamma-radiation which would permanently sterilize most human males and females may be of the order of 500 to 625 r.

In animals with relatively poor gonadal regenerative capacity, such as the human, chronic irradition may be relatively of more serious consequence, and this tends to be supported by data from experiments on dogs. It is such exposure which may constitute the greatest practical human hazard as far as sterility is concerned.

A few experimental data indicate greater radiosensitivity in prepubertal animals, especially foetuses.

G. Effects of Irradiation on Growth and Development

This section is concerned with post-natal development and growth and does not include a detailed discussion of the effects of irradiation on prenatal development and organogenesis *per se.*

Regenerative and repair processes of the body appear to be fairly sensitive to the effects of ionizing radiation and inhibition of these processes may be very persistent, especially if vascular integrity and patency are impaired. Much more quantitative investigation of these aspects of the problem is needed, under circumstances of both total-body and localized irradiation.

Quantitative studies with rats seem to indicate that growth, as measured by body weight, is decreased by repeated exposure to as little as 24 r per week of whole body irradiation. It has been shown that a significant decrease in body weight can be produced by a schedule of repeated whole body exposures which does not cause any decrease in levels of hemoglobin or absolute neutrophils.

Localized irradiation of the epiphysis has been shown to cause measurable inhibition of bone growth and shortening of bones in humans and animals. In general, the greatest effect is seen in the youngest animals. Localized irradiation of the jaws has been followed by decrease in tooth growth.

Studies on children exposed to the atomic bomb in Japan indicate that growth and maturation are slightly retarded. The production of malformation by exposure of embryos or foetuses to irradiation has been investigated extensively in experimental animals. The production of relatively severe malformations in viable human offspring by irradition *in utero*, known from some clinical experience, has been confirmed by studies in Japanese atomic bomb survivors. The study of post-natal effects upon growth produced by irradiation of the foetus, however, has been neglected generally.

An extensive series of measurements on 4800 children at 6, 7, and 8 years after exposure to the atomic bomb at Hiroshima revealed in general that growth was retarded and maturation delayed. In another study involving several hundred children surviving the atomic bombings at Hiroshima and Nagasaki in 1945 and studied in the 2nd, 4th, and 5th years after irradiation, it was reported that the physical growth and development of the children were adversely affected, and the resulting retardation of their height, weight, and skeletal development was still evident at the end of 1950. The investigators expressed the belief that factors other than radiation may have contributed to the effects described. This study has been considered by some to be at variance with other studies on the same material.

Studies of children who had been irradiated *in utero* during the atomic bombings in Japan are noteworthy. In one series of 74 irradiated and 91 control children, roentgenographic survey failed to reveal differences in incidence of skeletal abnormalities between the exposed and control groups. A study of 4400 individuals who had been exposed to the bomb *in utero* or as children up to age 10 revealed 33 cases of microcephaly, with associated mental retardation

in 15 cases, and 19 cases of leukemia. There were also cases of mild visual disability among those now 16 to 19 years old who were exposed within 1800 meters of hypocenter. Observations on 205 children 4½ years old, who had been exposed at Hiroshima within approximately 1200 meters of hypocenter during the first half of uterine life, indicate that central nervous system defects were produced.

The mechanisms of growth inhibition by radiation are not understood. Biochemical and cytologic studies of animals in which growth has been inhibited appears to be indicated. The late effects, including life-span studies of exposure to ionizing radiation in pre-natal and early life merit further study.

IV. COMMENTS AND RECOMMENDATIONS

It appears likely that the after-effects of whole body external irradiation are quite general, consisting of irreversible injury to all the organ systems to at least some degree. Specific organ pathology or the incidence of specific disease is not prominent, however, except following large single doses or high intensity chronic irradiation and in even these cases, for the most part, the disease entities are not unusual, but occur earlier in the life of the animal. Although not clearly established at low chronic dosage levels premature aging with shortening of life span appears to be common to all whole body exposure. This effect is sufficiently large that it may provide a better criterion for limitation of exposure than increased incidence of specific disease.

The effects of partial body irradiation on life-span have not been studied except with internally deposited radioactive materials for which the local dosage is not usually well known. Consequently, comparisons with whole body effects are difficult. With partial body irradiation, when highly localized at least, local pathology is probably the best criterion for exposure limitation.

Because most pathologic studies have been made on animals dying or sacrificed during chronic irradiation, rather than after exposure and repair, the permanent after-effects have not been well separated from the total injury and related quantitatively to dose.

Animals prematurely aged by irradiation have not been studied to determine those changes which presumably have occurred in their physiological efficiency.

Except for alterations of pre-natal development very little is known of the after-effects of either whole or partial body irradiation in the young in comparison to mature animals.

Agents which, when administered to animals at the time of irradiation, permit them to survive doses which are ordinarily lethal, do not, according to scanty existing information, reduce the late effects. Consideration should be given to the possibility of increasing the reversibility of radiation injury and of diminishing thereby the late effects.

In anticipation that definitive information on man can be approached only by extrapolation from animals along with comparison to meager human data, studies on animals should be widely extended, not only with respect to experimental numbers to increase the accuracy of observation, but also to a greater variety of species to ascertain the generality of quantitative dose-effect relations.

V. REFERENCES

This report is based largely on the following detailed reviews, which were prepared in anticipation of the report. These reviews contain bibliographic references to most of the specific experimental works and reviews consulted in the preparation of the report.

(A LETTER FROM JAPAN)

ST. PAUL'S UNIVERSITY,
(RIKKYO DAIGAKU),
Ikebukuro, Tokyo, Japan, June 4, 1957.

Dr. C. HOLIFIELD,
Chairman of Radiation Subcommittee of Joint Committee on Atomic Energy, United States of America.

DEAR DR. HOLIFIELD: Enclosed is a copy of our comment on Dr. Libby's paper which was publicated at the meeting of the American Physical Society on April 26, 1957. I should appreciate it very much if you would kindly arrange our paper to offer at the committee.

Very sincerely yours,

MITUO TAKETANI, *Professor,*
IWAO OGAWA, *Assistant Professor,*
TADAYOSHI DOKE, *Assistant Professor,*
Department of Physics, St. Paul's University, Tokyo, Japan.

1. It seems quite sure that the data submitted by many nations to the Scientific Committee of the United Nations in April 1957 show no significant differences among these data concerning the levels and distributions of strontium 90 accumulated on the ground at present. However, with respect to the estimated value in the future we find appreciable differences, e. g., contrary to Dr. Libby, who insists that the levels of strontium 90 accumulated on the ground in the United States may not exceed the present amount if the nuclear explosion tests are stopped, the British scientists made the estimate of the amount as about 2.5 times of the present one in about 10 years. Although these differences come from the diverse estimates of the amount of strontium 90 remained in the stratosphere, based on our own data we have made the nearly same estimate as that of the British scientists.

2. According to Dr. Libby most people obtain their calcium through milk products. Then he assumes a discrimination factor of 20 against strontium 90 from the soil to the human bones. However, in the world there are many people who obtain primely their calcium through vegetables, especially in the Orient. In such a case, it seems quite natural that we should estimate the discrimination factor appreciably lower than the case of depending on milk products. For instance, in Japan 50 percent of calcium source for the people is rice. Accordingly we should naturally estimate the discrimination factor as about 4.

3. Taking into account the above discussions, we may conclude that, if nuclear weapon tests are continued at the present rate for the coming three or four years, the radiation dose from strontium 90 deposited in the bones of those who have the Japanese-like food habit will reach the average value of the dose from natural radiations, e. g., cosmic ray, terrestrial radiation, and natural Ra in human bones.

4. Furthermore, Dr. Libby, in his report, seems to have made a definite mistake about the hazards by the very weak radiation. He investigated the correlation between the altitude difference of the cosmic ray and occurrence of bone cancer and leukemia, but such a method is nonsense unless the many kinds of natural radiations other than the cosmic ray are taken into account, because their doses are three times of the doses irradiated by cosmic ray, and these variation from place to place is rather appreciable.

On such a problem, the authorities in the MRC report of UK state that: "On the whole the experiments seem in favour of a proportionality between the frequency of tumours produced in a given length of time and the amount of radiative material in the body even at low dose levels."

If we accept such a proportionality, we may be able to conclude that the number of people in whose bodies cancers are produced will increase considerably. However, we consider that the detection of such hazards due to the nuclear weapon tests is very difficult, because a *percentage* of the occurrence of the hazards is quite small, although large in the absolute number. Taking into consideration the probability mentioned above, we should keep the dose from strontium 90 in human bone lower than that from natural radiation as possible.

5. Concerning caesium 137 very few data are available at present, and so we can not as yet make any accurate estimate of the amount in the human body in the future. However, this element seems to become an important material in the future if nuclear test explosions are continued at the present rate.

6. Recently we have continuously detected a considerable amount of long-life α-emitter in the air. Although we have not yet completed the radio-chemical analysis, we are afraid that there may be included an appreciable fraction of elements with very low MPC., such as Plutonium 239.

JAPANESE GENETICISTS ON RADIATION

The following "Statement concerning the genetic effects of radiation upon man" was prepared in April by the Genetics Society of Japan and the Japan Society of Human Genetics and sent out by them to a number of colleagues in other countries.

"With the increasing utilization of atomic energy, man inevitably has greater chance of being exposed to radiation than he has previously had. Generally speaking, any kind of radiations causes some damage to organisms. Particularly, their genetic effect is serious for the following reasons:

"1. It has been demonstrated by many experiments that radiations induce genetic changes or 'mutations' in organisms. Man cannot be exempt from this rule. Some such mutations occur naturally, but radiations raise their frequency.

"2. The great majority of these mutations are deleterious to mankind. Their effect may appear in the next generation, but more commonly only in subsequent generations. Therefore, the apparent escape of the next generation from such an effect does not ensure the genetic safety of all descendants.

"3. The incidence of mutation increases in proportion to the total dose of radiation given to the gonad. Whether irradiation is continuous or intermittent, the same amount of mutation is induced in either case, provided that the total dose is the same, since the mutation which was once induced persists even after the end of irradiation and is handed down to progeny. Thus the genetic effect of radiations through the gonad is fundamentally distinct from their direct damage to the body, which may disappear after the end of irradiation.

"4. Human population acquires natural mutations which are of very low incidence. These mutations are removed by natural selection, and the newly-appearing mutations and those removed by selection are mutually balanced, the incidence of mutant genes is thus kept in equilibrium. Additional mutations artificially induced by irradiation cause the break-down of this equilibrium, and an increase of the mutant genes possessed by the population. Such a change will lead to a gradual increase of individuals handicapped in physical strength or in mental capacity, increases the sacrifices of individuals and the burdens of the society, and leads to eventual disaster for mankind.

"From what has been pointed out above, we are led to conclude that any amount of radiation, however small it may be, is deleterious to the heredity of man. Although a certain dose has been set as 'permissible' for people engaged in the operation of X-rays and radioactive apparatus or substances, this is only aimed at the safety and health of those people themselves. However, as far as the gentic effect on their descendants is concerned, there is no theoretical limit below which danger may be entirely excluded.

"Although there can be hardly any question about the necessity for the peaceful utilization of atomic and other radiation energies, it is still all the more important to guard against any misuse or misoperation of such energies. This is not only for the safety of the present generation, but also for the health and prosperity of our descendants. Also, we must be on guard against the gentic effects of atomic or hydrogen bomb tests, which increase the level of radioactive contamination in the air and water.

"Under such circumstances, we geneticists eagerly hope that the general public will realize the urgency of the question at issue, and that effective means for its solution will be taken promptly."

APPENDIX 6

A SELECTION OF CORRESPONDENCE AND STATEMENTS TO AND BY THE ATOMIC ENERGY COMMISSION CONCERNING THE SCIENTIFIC AND TECHNICAL ASPECTS OF FALLOUT.

STATEMENT BY LEWIS L. STRAUSS, CHAIRMAN, UNITED STATES ATOMIC ENERGY COMMISSION, FEBRUARY 1955

At a news conference on December 17, 1954, I stated that the staff of the Atomic Energy Commission was studying the subject of fallout and expressed the hope that information about it would be made public at a later date. "Fallout" is the word now applied to a phenomenon that follows the explosion of a nuclear weapon. Such an explosion, if the fireball touches the surface of the earth, draws up large amounts of materials into the bomb cloud. These materials subsequently fall back to earth as radioactive particles over a large area, mostly down-wind and relatively close to the point of explosion—although the lighter particles are carried great distances. The main radioactivity of fallout decreases very rapidly with time—for the most part, within the first hours after the explosion. An in-the-air explosion where the fireball does not touch the earth's surface does not produce any serious radiological fallout hazard.

Since nuclear weapons are in possession of the USSR, the Commission believes the American people wish to be informed regarding the dangers of nuclear explosions and the measures which individuals can take to protect themselves if an atomic attack should ever occur. Therefore, the Commission has condensed in the attached Report the information which can be made public at this time on the effects of the explosions of high-yield nuclear weapons.

The following excerpts and summarized sections contain the highlights of the Report itself.

FALLOUT PATTERN OF 1954 TEST IN THE PACIFIC

The very large thermonuclear device tested at Bikini Atoll on March 1, 1954, was detonated on a coral island and the ensuing fallout contaminated an elongated, cigar-shaped area extending approximately *220 statute miles down-wind and varying in width up to 40 miles*. In addition, there was a contaminated area up-wind and cross-wind extending possibly 20 miles from the point of detonation. Data was collected from 25 points on 5 atolls located from 10 to 330 miles down-wind (generally east) from Bikini Atoll. Due to an unexpected shift in the direction of the prevailing winds in the higher altitudes, the fallout missed the observation rafts that had been placed farther north previous to the test firing. The estimated contour of the pattern of fallout is, therefore, based only in part on data obtained from actual measurements and partly on calculations.

Data from this and other tests permits *estimates* of casualties which would have been sufferer within this contaminated area if it had been populated. These *estimates* assume: (1) that the people in the area would ignore even the most elementary precautions; (2) that they would not take shelter but would remain out of doors completely exposed for about 36 hours; and (3) that in consequence they would receive the maximum exposure. Therefore, it will be recognized that the estimates which follow are what might be termed *extreme* estimates since *they assume the worst possible conditions.*

On the basis of our data from this test and other information, it is estimated that. following the March 1, 1954, test explosion, there was sufficient radioactivity in a down-wind belt about 140 miles in length and of varying width up to 20 miles to have seriously threatened the lives of nearly all persons in the area *who took no protective measures.*

Some distance farther from the point of detonation, at about 160 miles down-wind and along the exis of the ellipse, the amount of radioactivity would have seriously threatened the lives of about one-half of the persons in the area who took no protective measures.

Near the outer edge of the ellipse, or approximately 190 miles down-wind, it is estimated that the level of radioactivity would have been sufficient to have seriously threatened the lives of 5 to 10 percent of any persons who might have remained exposed out of doors for all of the first 36 hours.

Thus, about 7,000 square miles of territory down-wind from the point of burst was so contaminated that survival might have depended upon prompt evacuation of the area or upon taking shelter and other protective measures.

At a distance of 220 miles or more down-wind, it is unlikely that any deaths would have occurred from radioactivity even if persons there had remained exposed up to 48 hours and had taken no safety measures.

The estimates cited above do not apply uniformly throughout the contaminated area inasmuch as the intensity of radioactivity within a region of heavy fallout will vary from point to point, due to such factors as air currents, rain, snow, and other atmospheric conditions. Because of this and because most persons, if given sufficient warning, probably would evacuate the area or take shelter and other precautionary measures, the actual percentage of fatalities could reasonably be presumed to be considerably smaller than these extreme estimates.

PROTECTION AGAINST FALLOUT

In the area of heavy fallout the greatest radiological hazard is that of exposure to *external* radiation, which can be greatly reduced by simple precautionary measures. Exposure can be reduced by taking shelter and by simple decontamination measures. Test data indicates that the radiation level, i. e., the rate of exposure, indoors on the first floor of an ordinary frame house in a fallout area would be about one-half the level out of doors. Even greater protection would be afforded by a brick or stone house. Taking shelter in the basement of an average residence would reduce the radiation level to about one-tenth that experienced out of doors. Shelter in an old-fashioned cyclone cellar, with a covering of earth three feet thick, would reduce the radiation level to about 1/5000, or down to a level completely safe, in even the most heavily contaminated area. Designs of shelters of simple yet effective construction have been prepared by the Civil Defense Administration and are available to the public.

Radioactive material deposited during the fallout may or may not be visible but would be revealed by radiation detection instruments such as Geiger counters. Any falling dust or ash that can be seen down-wind within a few hours after a nuclear explosion should be regarded as radioactive until measured by a radiation detection instrument.

Care should be taken to avoid the use of solid foods or liquids that may contain fallout particles.

If fallout particles come into contact with the skin, hair, or clothing, prompt decontamination precautions such as have been outlined by the Federal Civil Defense Administration will greatly reduce the danger. These include such simple measures as *thorough bathing of exposed parts of the body and a change of clothing.*

INTERNAL RADIATION EFFECTS

Two other factors must be considered in evaluating possible hazards from radioactive fallout. The first is the effect of internal radiation from fallout particles swallowed in food or liquids. The second is the effect of radiation upon the germ cells which transmit inherited characteristics from one generation to another. It should be noted that in neither case is there reason to believe that weapons testing programs of the United States have resulted in any serious public hazard.

The radioactive forms of strontium and iodine are the constituents of fallout which are of principal concern as internal sources of radiation through ingestion. The concentrations of these substances from nuclear detonations to date have been monitored at many localities, and the amounts detected have been insignificant, compared to concentrations which would be hazardous.

GENETIC EFFECTS OF RADIATION

There is a wide range of admissible opinion as to the genetic effects which radiation might have upon future generations, and conclusive data is not available at present on which to base an incontrovertible forecast. However, it is important to recognize that the average amount of radiation exposure received

by residents of the United States from all nuclear detonations to date has been about the same as the exposure received from one chest X-ray. The Commission's medical and biological advisers do not believe that this small amount of additional exposure is any basis for serious concern at this time.

BLAST AND HEAT EFFECTS

Two important characteristics of any nuclear explosion, other than those from fallout, are the effects of blast and heat, which are of the same nature for a thermonuclear bomb as for the earlier and smaller atomic bombs. The intensity and area of the blast and heat effects increase in relation to the greater energy yield of the explosion. Much information on these two effects has already been published by the Atomic Energy Commission, but it might be recalled that an atomic bomb of the earliest type, equivalent to 20,000 tons of TNT, would produce blast and heat sufficient to destroy, or damage severely, buildings within a radius of more than one mile from the explosion point. The United States has developed fission bombs many times as powerful as the first atomic bombs, and hydrogen weapons in the ranges of millions of tons (megatons) of TNT equivalent.

PROTECTION AGAINST BLAST AND HEAT

The hazard from both burn and blast effects well *outside* the central target area would be reduced greatly by shelter. Clothing or almost any kind of shelter would reduce the danger of direct burns, although there might be danger of clothing and structures becoming ignited. Also, shelter would materially reduce the hazard of blast injury by affording protection against flying or falling debris. As is generally known, the shelter afforded by ordinary city buildings would not suffice within the central area surrounding the point of explosion of a large nuclear weapon. For this reason, the Federal Civil Defense Administration recommends evacuation of the central areas of target zones on early warning of approaching attack.

FALLOUT FROM NEVADA TESTS

Only relatively small nuclear test explosions are conducted at the Nevada Test Site, in contrast to the tests of high-yield thermonuclear devices at the Pacific Proving Grounds. In Nevada, as well as in the Pacific, all tests are planned for times when forecast weather conditions minimize the possibility of fallout hazard. High air bursts at the Nevada Test Site have produced no significant fallout; heavy fallout from near-surface explosion has extended only a few miles from the point of burst. The hazard has been successfully confined to the controlled area of the Test Site. The highest actual dose of radiation at an off-site community has been estimated to be *less than one-third of the greatest amount of radiation which atomic energy workers are permitted to receive each year under the Atomic Energy Commission's conservative safety standards.*

CONCLUSION

In the event of war involving the use of atomic weapons, the fallout from large nuclear bombs exploded on or near the surface of the earth would create serious hazard to civilian populations in large areas outside the target zones. The Atomic Energy Commission hopes that these dangers will never be experienced by mankind. However, until the possibility of an atomic attack against us is eliminated by a *workable international plan for general disarmament*, the study and evaluation of the effects of weapons which might be used against us and the improvement of our means of self-defense are a paramount duty of our Government.

A REPORT BY THE UNITED STATES ATOMIC ENERGY COMMISSION ON THE EFFECTS OF HIGH-YIELD NUCLEAR EXPLOSIONS

1. Considerable information on the effects of the explosions of atomic weapons has been made public by the Government since the first nuclear detonations in 1945. The handbook, "The Effects of Atomic Weapons", published in 1950, is being revised and brought up to date to include the effects of thermonuclear weapons, as a result of the most recent tests at the Pacific Proving Grounds. References to the effects of thermonuclear explosions have been made in several

official statments, beginning with Chairman Strauss' description of the phenomenon of "fallout" at a White House news conference on March 31, 1954. The following statement is designed to condense and correlate information, some of which already has been made public and other portions of which have been of a classified nature until now.

2. The effects of nuclear tests are evaluated for civil defense planning as well as for military and technological purposes. So long as nuclear weapons are in possession of any unfriendly power, the Commission believes the American public will wish to be as fully informed as possible as to the nature and extent of the dangers of nuclear attack and of the protective measures that can be taken by individuals and communities to avoid or minimize those dangers if we should be attacked.

3. Test conditions, which must necessarily form the principal basis of evaluating the effects of nuclear explosions, may differ markedly from those which might be expected if nuclear weapons were used against our population in wartime. It would be difficult to predict the size or kind of bomb an enemy might use against us in event of war, the exact means of its delivery, the height at which it would be exploded, or the number of bombs which might reach a given target. Nevertheless, the facts to follow are the fundamental ones at this time.

FOUR EFFECTS OF DETONATIONS

4. A nuclear detonation produces four major characteristics—blast, heat, immediate nuclear radiation, and residual radioactivity. Of these, the first three are essentially instantaneous, while the fourth has a more protracted effect. The phenomena of blast, heat, and nuclear radiation from the detonation of a thermonuclear bomb are of the same nature as those of earlier and smaller atomic bombs. The nature of the phenomena is, in general terms, standardized whether the bomb be a 20,000-ton (TNT equivalent) atomic weapon or a thermonuclear one of many times that power. The intensity and area of the blast, heat, and nuclear radiation increase in relation to the greater energy yield of the explosion. Information on these effects has been extensively publicized; therefore, the remainder of this report deals principally with effects other than heat and blast.

5. Residual radioactivity, although in no sense exclusive to high yield thermonuclear detonaions, does become a mater of major concern when a large thermonuclear device of the type used in the 1954 tests in the Pacific is exploded. The fallout of radioactivity from such an explosion, may, under certain conditions, settle over wide areas. Therefore, the extent and severity of this radioactive fallout has been a subject of continuing study since the first full-scale thermonuclear tests at the Pacific Proving Grounds on November 1, 1952. The results of these studies and of our evaluation of data obtained from the latest tests in the Pacific in March, 1954, are described in subsequent parts of this report.

6. It should be noted that if we had not conducted the full-scale thermonuclear tests mentioned above, we would have been in ignorance of the extent of the effects of radioactive fallout and, therefore, we would have been much more vulnerable to the dangers from fallout in the event an enemy should resort to radiological warfare against us.

BLAST AND HEAT EFFECTS

7. The effects of blast and heat from a nuclear explosion are relatively localized. One A-bomb of the earliest type equivalent to 20,000 tons of TNT (20 kilotons) would produce blast sufficient to destroy or damage severely residences within a radius of more than one mile from the point of burst. Within a radius of about a mile and a half, residences would be so damaged as to be unusable without repairs. A principal hazard to human beings would come from flying and falling debris and from fires due to such causes as broken gas and electric lines or overturned stoves. The area in which injuries to human beings would be caused by blast, therefore, would be about the same as the area of damage to structures.

8. The United States, as announced previously, has developed fission bombs many times as powerful as the first A-bombs, and hydrogen weapons in the ranges of millions of tons (megatons) of TNT equivalent. For these larger weapons, the blast effects can be calculated approximately by means of a scaling law, namely, the distance at which a given blast intensity is produced varies as the cube roots of the yields of the explosions.

9. Similarly, the heat and burn effects of nuclear explosions can be estimated from accumulated data. These effects, of course, are influenced by prevailing atmospheric conditions. The time element also is a prime factor. Very large weapons deliver heat over an appreciably greater period of time than smaller weapons. A given quantity of heat from a high-yield weapon, delivered over a longer period of time, will produce somewhat *less* severe burns than the same quantity of heat from a nominal detonation.

PROTECTION AGAINST BLAST AND HEAT

10. The hazard from both burn and blast effects in the *outer* affected areas would be reduced greatly by shelter. Clothing or almost any kind of shelter would reduce the danger of direct burns, although there might be some danger of clothing and structures becoming ignited. Also, shelter would materially reduce the hazard of blast injury by affording protection against flying or falling debris. The Federal Civil Defense Administration has made extensive studies of shelters and has issued plans for several simple and inexpensive types which can be utilized by householders. As is generally known, the shelter afforded by ordinary city buildings would not suffice within the central area surrounding the point of burst of a large nuclear weapon. For this reason, the Federal Civil Defense Administration recommends evacuation of the central areas of target zones on early warning of approaching attack.

RADIATION EFFECTS

11. The immediae nuclear radiation, i. e., the neutrons and gamma rays released instantaneously with the explosion of a large weapon on or near the ground, does not present a serious hazard beyond the area where heat and blast are of great concern.

FALLOUT RADIATION

12. However, particles with residual radioactivity produced by a detonation (as opposed to the immediate nuclear radiation) may fall out over an area much larger than that affected by blast and heat, and over a longer period of time. All nuclear detonations produce radioactive materials, but the nature and extent of the radioactive fallout depends on the conditions under which the bomb is fired. The main radioactivity of a bomb's fallout increases very rapidly with time—for the most part, within the first hours after the detonation.

FALLOUT FROM IN-THE-AIR DETONATIONS

13. In an in-the-air explosion where the fireball does not touch the earth's surface, the radioactivity produced in the bomb condenses only on solid particles from the bomb casing itself and the dust which happens to be in the air. In the absence of material drawn up from the surface, these substances will condense with the vapors from the bomb and air dust to form only the smallest particles. These minute substances may settle to the surface over a very wide area—probably spreading around the world—over a period of days, or even months. But they descend extremely slowly with the result that, by the time they have reached the earth's surface, the major part of their radioactivity has been dissipated harmlessly in the atmosphere, and the residual contamination is widely dispersed.

FALLOUT FROM SURFACE DETONATIONS

14. If, however, the weapon is detonated on the surface or close enough so that the fireball touches the surface, then large amounts of material will be drawn up into the bomb cloud. Many of the particles thus formed are heavy enough to descend rapidly while still intensely radioactive. The result is a comparatively localized area of extreme radioactive contamination and a much larger area of some hazard. Instead of wafting down slowly over a vast area, the larger and heavier particles fall rapidly before there has been an opportunity for them to decay harmlessly in the atmosphere and before the winds have had an opportunity to scatter them.

15. The area of hazard from radioactive fallout from a surface or near-surface explosion of a thermonuclear weapon is much larger than the areas seriously affected by heat and blast. The large radioactive cloud of a thermonuclear explosion rises with great rapidity to the highest levels of the atmosphere

and spreads over hundreds of square miles in the first hours. During this time the winds toss the extremely radioactive particles about and the pattern of the radioactive fallout is determined by the size of the particles and by the direction and velocities of the winds, including those up to 80,000 feet and above. The nature of the surface of the earth on which the bomb is fired also must be taken into consideration. Because of these variables, it is impossible to apply a single fallout pattern to all thermonuclear detonations, even test explosions conducted under selected conditions. However, with adequate knowledge of atmospheric conditions, including wind directions and velocities up to high levels and meteorological reports, the fallout region for any detonation usually can be predicted with considerable accuracy. In general terms, the region of severe fallout contamination from the detonation of a thermonuclear weapon fired on or near the surface can be described as an elongated, cigar-shaped area extending down-wind from the point of burst.

FALLOUT PATTERN OF 1954 TEST IN THE PACIFIC

16. The very large thermonuclear device fired at the Bikini Atoll on March 1, 1954, was exploded on a coral island. Coral consists of calcium carbonate, thus the detonation's radioactivity was spread by particles consisting largely of unslaked lime which, during the hours of descent, was slaked by moisture in the atmosphere. These particles ranged between 1/1000th and 1/50th of an inch in diameter and were, on the average, somewhat adhesive. The prevailing winds were westerly so the bomb cloud moved generally to the east and deposited the radioactive particles in varying amounts over an elliptical or cigar-shaped area. About 160 (statute) miles down-wind from the point of burst the early fallout was observed in the form of fine particles which looked like snow. Fallout began there about eight hours after the detonation and continued for several hours.

17. The roentgen is the commonly accepted unit of measurement of radiation dosage. A dose of about 25 roentgens of radioactivity received by a person over a brief space of time will produce temporary changes in the blood. A dose of some 100 roentgens received in a short interval may produce nausea and other symptoms of radiation sickness. About 450 roentgens delivered over a day or so might be fatal to approximately half of the persons so exposed. However, because of the body's repair processes, a total radiation dose which would be serious if incurred in a few minutes would produce much less effect if spread over a period of years. These statements may be helpful in understanding the data which follow.

18. The test explosion, at ground surface, contaminated a cigar-shaped area extending approximately *220 statute miles down-wind and varying in width up to 40 miles.* In addition, there was a contaminated area up-wind and cross-wind extending possibly 20 miles from the point of detonation. Data was collected from 25 points on 5 atolls located from 10 to 330 miles down-wind (generally east) from Bikini Atoll. Due to an unexpected shift in the direction of the prevailing winds in the higher altitudes, the fallout missed the observation rafts that had been placed farther north previous to the test firing. The estimated contour of the pattern of fallout is, therefore, based only in part on data obtained from actual measurements and partly on extrapolation, i. e., calculations based on known data, including factual information obtained during previous tests of smaller devices.

19. Data from this test permits *estimates* of casualties which would have been suffered within this contaminated area if it had been populated. These estimates assume: (1) that the people in the area would ignore even the most elementary precautions; (2) that they would not take shelter but would remain out of doors completely exposed for about 36 hours; and (3) that in consequence they would receive the maximum exposure. Therefore, it will be recognized that the estimates which follow are what might be termed *extreme estimates* since *they assume the worst possible* conditions.

20. On the basis of our data from this and other tests, it is estimated that, following the test explosion on March 1, 1954, there was sufficient radioactivity in a downwind belt about 140 miles in length and of varying width up to 20 miles to have seriously threatened the lives of nearly all persons in the area who *did not take protective measures.* During the actual tests, of course, there were no people in this zone. Inside Bikini Atoll at a point 10 miles downwind from the explosion it is estimated that the radiation dosage was about 5,000 roentgens for the first 36-hour period after the fallout. The highest radiation

measurement outside of Bikini Atoll indicated a dosage of 2300 roentgens for the same period. This was in the northwestern part of the Rongelap Atoll, about 100 miles from the point of detonation. Additional measurements in Rongelap Atoll indicated dosages, for the first 36 hour period, of 2000 roentgens at 110 miles, 1000 roentgens at 125 miles, and, farther south, only 150 roentgens at 115 miles from Bikini.

21. Some distance farther from the point of detonation, at about 160 miles down-wind and along the axis of the ellipse, the amount of radioactivity would have seriously threatened the lives of about one-half of the persons in the area who *failed to take protective measures.* It is estimated that the radiation dosage at that point was about 500 roentgens for the first 36-hour period.

22. Near the outer edge of the cigar-shaped area, or approximately 190 miles down-wind, it is estimated that the level of radioactivity would have been sufficient to have seriously threatened the lives of 5 to 10 percent of any persons who might have remained exposed out of doors for the first 36 hours. In this area the radiation dosage is estimated at about 300 roentgens for the first 36 hour period.

23. Thus, about 7,000 square miles of territory down-wind from the point of burst was so contaminated that survival *might* have depended upon prompt evacuation of the area or upon taking shelter and other protective measures.

24. At a distance of 220 miles or more down-wind, it is unlikely that any deaths would have occurred from radioactivity even if persons there had remained exposed up to 48 hours and had taken no safety measures.

25. The estimates cited above do not apply uniformly throughout the contaminated area inasmuch as the intensity of radioactivity within a region of heavy fallout will vary from point to point due to such factors as air currents, rain, snow, and other atmospheric conditions. Because of this and because most persons, if given sufficient warning, probably would evacuate the area or take shelter and other precautionary measures, the actual percentage of deaths could reasonably be presumed to be considerably *smaller* than these extreme estimates.

PROTECTION AGAINST FALLOUT

26. In an area of heavy fallout the greatest radiological hazard is that of exposure to *external* radiation. Simple precautionary measures can greatly reduce the hazard to life. Exposure can be reduced by taking shelter and by utilizing simple decontamination measures until such times as persons can leave the area. Test data indicate that the radiation level, i. e., the rate of exposure, indoors on the first floor of an ordinary frame house in a fallout area would be about one-half the level out of doors. Even greater protection would be afforded by a brick or stone house. Taking shelter in the basement of an average residence would reduce the radiation level to about one-tenth that experienced out of doors. Shelter in an old-fashioned cyclone cellar, with a covering of earth three feet thick, would reduce the radiation level to about 1/5000, or down to a level completely safe, in even the most heavily contaminated area. Designs of shelters of simple yet effective construction have been prepared by the Civil Defense Administration and are available to the public.

27. Radioactive material deposited during fallout may or may not be visible but would be revealed by radiation detection instruments such as Geiger counters. Any falling dust or ash that can be seen down-wind within a few hours after a nuclear explosion should be regarded as radioactive until measured by a radiation detection instrument and found to be harmless.

28. Care should be taken to avoid the use of solid foods or liquids that may contain fallout particles.

29. If fallout particles come into contact with the skin, hair or clothing, prompt decontamination precautions such as have been outlined by the Federal Civil Defense Administration will greatly reduce the danger. These include such simple measures as *thorough bathing of exposed parts of the body and a change of clothing.*

30. If persons in a heavy fallout area heeded warning or notification of an attack and evacuated the area or availed themselves of adequate protective measures, the percentage of fatalities would be greatly reduced even in the zone of heaviest fallout.

FALLOUT FROM NEVADA TESTS

31. Only relatively small nuclear test explosions are conducted at the Nevada Test Site, in contrast to the tests of high-yield thermonuclear devices at the Pacific Proving Grounds. In Nevada, as well as in the Pacific, all tests are

planned for times when forecast weather conditions minimize the possibility of fallout hazard. Methods of forecasting weather patterns in these areas are improving steadily. High air bursts at the Nevada Test Site have produced no significant fallout; heavy fallout from near-surface explosions has extended only a few miles from the point of burst. The hazard has been successfully confined to the controlled area of the Test Site. The highest actual dose of radiation at an off-site community has been estimated to be *less than one-third of the greatest amount of radiation which atomic energy workers are permitted to receive each year under the Atomic Energy Commission's conservative safety standards.*

INTERNAL RADIATION EFFECTS

32. Several basic facts should be kept in mind in evaluating the hazard from fallout radiation. First, radiation is not a new phenomenon created by the explosions of fission and thermonuclear weapons. Since the beginning of life, living things have been exposed constantly to radiation from natural sources. Cosmic rays from space constantly pass through our bodies. We are exposed to "background" radiation from radium and radon in the soil, water and air. Our bodies have always contained naturally radioactive potassium and carbon.

33. As pointed out earlier, detonations of all atomic weapons produce radioactivity, a portion of which is carried to high altitudes and over great distances in the form of fine particles. The percentage of this radioactivity which travels beyond the relatively near area of the explosion depends largely on the conditions under which the bomb is fired, the percentage being higher for in-the-air bursts where the fireball does not touch the earth's surface. The most widespread radioactivity is produced only by the longer-lived fission products, since the radioactivity of the shorter-lived products decays and disappears before the particles come down to earth in a matter of days, weeks, months, and even years. The longer-lived radioactive products may be distributed over the entire earth. However, as the particles are carried farther and farther to remote areas, the possibility of significant amounts of fallout decreases.

RADIOSTRONTIUM FALLOUT

34. One of the most biologically important radioactive substances found in fallout is strontium–90. It has a long lifetime—nearly 30 years on the average. Radiostrontium has a chemical similarity to calcium and, therefore, when taken into the body it has a tendency to collect in the bones. Radiostrontium can enter the body in two ways—by inhaling or by swallowing. Normally, the amount inhaled would be small compared with the amount one might swallow. Fallout material deposited directly on edible parts of plants may be eaten along with the plants, but washing the plants before they are eaten would remove most of this radioactive material. However, rainfall carrying the radiostrontium down to earth may deposit it in the soil where it can be taken up, in part, by plants and incorporated into plant tissues, later to be eaten by humans or by grazing animals which, in turn, provide food for humans.

35. Since the start of nuclear tests, careful measurements have been made of the distribution of radiostrontium over the earth's surface, in the soils, in plants and animal tissues, in the oceans, in rain, in the atmosphere and in all forms in which it might be expected to occur. The results of this study are reassuring. The amount of radiostrontium now present in the soil as a result of all nuclear explosions to date would have to be increased many thousand times before any effect on humans would be noticeable.

RADIOIODINE FALLOUT

36. Among the shorter-lived fission products involved in the study of internal radiation, the most biologically important is radioiodine–131 with an average life of only 11.5 days. Even though this product may be widely spread after a nuclear explosion, the possibility of serious hazard is limited by its relatively short life. Like the nonradioactive form of the element, it concentrates in the thyroid gland and, in excessive quantity, conceivably could damage the thyroid cells.

37. Scientists of the Atomic Energy Commission have estimated that the average exposure of people in the United States from radioiodine in the fallout from the entire series of tests in the spring of 1954 was only a few percent of the annual dose that can be received year after year and still have no noticeable effects.

38. These two isotopes—radiostrontium and radioiodine—constitute the principal internal hazards from the radioactivities produced by the detonations of atomic weapons, both fission and thermonuclear. The Atomic Energy Commission has been engaged for three years in a broad study of the radioactive forms of these isotopes and conducts year-round monitoring of these radioactivities in many locations. Any accumulation of these materials can be detected with great sensitivity so that ample warning of potential hazard could be given long before any actual danger occurred from test detonations. The amounts of radiostrontium and radioiodine which have fallen outside the areas near the test sites as a result of all atomic tests up to now are insignificant compared to concentrations that would be considered hazardous to health.

GENETIC EFFECTS OF RADIATION

39. One other effect of radiation must be considered in evaluating the long-range possibilities of hazard from nuclear detonations. This is the possible genetic effect upon the germ cells which transmit inherited characteristics from one generation to another. At our present stage of genetic knowledge, there is a rather wide range of admissible opinion on this subject.

40. In general, the total amount of radiation received by residents of the United States from all nuclear detonations to date, *including the Russian and British tests* and all of our own tests in the United States and the Pacific, has been about one-tenth of one roentgen. This is only about 1/100th of the average radiation exposure inevitably received from natural causes by a person during his or her reproductive lifetime. It is about the same as the exposure received from one chest x-ray.

41. The medical and biological advisers of the Atomic Energy Commission believe that the small amount of additional exposure of the general population of the United States from our nuclear weapons testing program will not seriously affect the genetic constitution of human beings. Nevertheless, we are continuing our thorough study of the entire question and will continue to report our findings to the American people.

SUMMARY

42. The Atomic Energy Commission hopes that the information on nuclear weapons effects contained in the foregoing report will never be reflected in human experience as the result of war. However, until the possibility of an atomic attack is eliminated by a workable international plan for general disarmament, the study and evaluation of weapons effects and civil defense protection measures must be a necessary duty of our government.

43. Inevitably, a certain element of risk is involved in the testing of nuclear weapons, just as there is some risk in manufacturing conventional explosives or in transporting inflammable substances such as oil or gasoline on our streets and highways. The degree of risk must be balanced against the great importance of the test programs to the security of the nation and of the free world. However, the degree of hazard can be evaluated with considerable accuracy and test conditions can be controlled to hold it to a minimum. None of the extensive data collected from all tests shows that residual radioactivity is being concentrated in dangerous amounts anywhere in the world outside the testing area.

44. In the event of war involving the use of atomic weapons, the fallout from large nuclear bombs exploded on or near the surface would create serious hazards to civilian populations in large areas outside the target zones. However, as mentioned in the foregoing Report, there are many simple and highly effective precautionary measures which must be taken by individuals to reduce casualties to a minimum outside the immediate area of complete or near-complete destruction by blast and heat. Many of these protective measures, such as shelter and decontamination procedures, have been detailed by the Federal Civil Defense Administration.

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington 25, D. C., August 8, 1956.

Hon. CLINTON P. ANDERSON,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR SENATOR ANDERSON: Enclosed for the information of the Joint Committee on Atomic Energy are the Atomic Energy Commission's analyses on the following:

1. *The Biological Effects of Atomic Radiation*, a study by the National Academy of Sciences, 1956.
2. *The Hazards to Man of Nuclear and Allied Radiations*, a report by the United Kingdom Medical Research Council of June 1956.
3. *Race poisoning by Radiation*, an article by H. J. Muller, appearing in the Saturday Review, June 9, 1956.

Primary attention has been devoted to the two basic documents—the reports of the National Academy of Sciences and the United Kingdom Medical Research Council. These are competent, well written reports and we trust that an increased public understanding of the effects of atomic radiation will result from their publication. We note, however, that with the exception of the article "*Radioactive Fallout through September 1955*" by Eisenbud and Harley to be published this month in SCIENCE, there were no major data presented in either the National Academy of Sciences' report or the United Kingdom Medical Research Council report not already known to the Atomic Energy Commission and previously reported in open literature.

Except for some difference in the Strontium–90 data, the data, conclusions and recommendations of both reports were in good agreement considering the complexity of the problems and the independence of the two studies. The reports recommended an additional restriction as to the total radiation exposure to be permitted over a number of years. It is not anticipated that the reports will create any major change in our position regarding our weapons testing position or the Atomc-for-Peace program.

Or did they merely get to the point of recognizing a genetics hazard?

Both the NAS and the UK reports consider the genetics aspect of radiation as being paramount. It is with this factor principally in mind that upper limits of whole bodily exposure over a long period of time were recommended. Based on these recommendations and those forthcoming from the International Commission on Radiation Protection, the AEC may consider placing an upper limit of yearly exposure for atomic energy workers. However, the average exposure to atomic energy workers during past operations has been so far below the maximum permissible level that the placing of a yearly upper limit would not be expected to impose any major restriction.

The NAS report recommended an upper limit of 50 roentgens for *individual* exposure up to age 30, and 10r during the like period for the *general* populace. Except in the case of the March 1, 1954, incident involving intensive fallout in the Marshall Islands area, no individual outside the testing areas has been exposed to even the 10r maximum recommended for the populace as a result of fallout from the U. S. nuclear testing program. The NAS report estimates that if the nuclear weapons tests were continued at the present rate the average exposure for the general population of the United States over a 30-year period would be about one-tenth of a roentgen. In summary, the report was reassuring as regards nuclear weapons testing; it did not attempt to face up to the problems of an atomic war; and, finally, it was preoccupied with the potential hazards inherent in a developing era of large scale atomic power.

As to the Strontium–90 accumulating in the biosphere, the AEC will continue its extensive program of maintaining collection stations throughout the world and of analyses of the samples. This close and continuing checking system will provide ample warning of any significant upward trends in the Strontium–90 content of the biosphere before hazardous levels would be approached. It is indicated in the NAS report that the highest levels observed throughout the world are about 1/100 of the Academy's estimate of permissible concentration for the population as a whole. Furthermore, our knowledge of present pollution from radiostrontium is more exact and more extensive than that with respect to any other atmospheric pollution.

Sincerely yours,

K. E. FIELDS, *General Manager*.

(Enclosure 1)

CRITIQUE OF THE REPORT OF THE NATIONAL ACADEMY OF SCIENCES

THE BIOLOGICAL EFFECTS OF ATOMIC RADIATION BASED ON (1) "A REPORT TO THE PUBLIC," AND (2) "SUMMARY REPORT."

To understand and best evaluate the implications of this report it is important to bear in mind the background of the individual scientists who made the study and their relationship to the National Academy of Sciencies-National Research Council and to the Government.

The NAS-NRC is not a Government organization. True, it was established by President Lincoln in order to have a distinguished body of scientists with whom the Government could consult at the time of the Civil War. On the other hand, it is a self-perpetuating body of free American scientists who control the membership of the Academy without any Government appointments. While various Federal agencies may appoint representatives to the various divisions of the National Research Council (the operating body of the NAS), they serve to bring problems to the Council for advice, and not to control the actions or the opinions of Council.

In the case of this study, the President of the NAS, Dr. Detlev W. Bronk, called together some 100 American scientists to carry out the study as individual citizens. While some of the scientists were Government employees and top advisers to Government on scientific matters, they were not acting in these capacities in their participation in the study.

The study was undertaken largely as a result of the concern felt throughout the country following the March 1, 1954 thermonuclear test explosion at Bikini, as a result of which a number of Marshall Islanders and Japanese fishermen were irradiated by fallout debris from the explosion. Subsequently, a number of scientific bodies in the U. S. passed resolutions requesting that a study be made of the possible effects on the human race of continued nuclear weapons testing.

In April, 1955, the Rockefeller Foundation provided the NAS with funds for undertaking a very broad study of the effects of atomic radiation. The subject reports are the final fruits of this study, which will be a continuing one.

Whereas the AEC has always been aware of the possible hazards from fallout from surface bursts of atomic weapons (see "Effects of Atomic Weapons," 1952), it had been even more aware of possible hazards to nearby livestock and the public generally from serious accidents which could conceivably occur to large production reactors such as those at the Hanford Works. The Bikini fallout incident made it abundantly clear that fallout *was* important from the standpoint of continued weapons testing and as a factor in civil defense planning. The problem of radiation effects has been under continuing review by the AEC and by the joint U. S., U. K. and Canada Tripartite meetings. In addition, the AEC has contributed a major portion of the basic scientific data for the deliberations of the National Committee for Radiation Protection and the International Commission for Radiation Protection.

A few words are in order on the general approach of the NAS study committees. They did not include an evaluation of the effects of an atomic war. As Dr. Bronk stated in the press conference of June 12, 1956, he could not define an atomic war so he asked the committees to limit themselves to peacetime atomic energy activities including weapons testing.

In the Foreword to the Summary Report, Dr. Bronk stated: "The use of atomic energy is perhaps one of the few major technological developments of the past 50 years in which careful consideration of the relationship of a new technology to the needs and welfare of human beings has kept pace with its development. Almost from the very beginning of the day of the Manhattan Project careful attention has been given to the biological and medical aspects of the subject. By contrast, the automobile revolutionized our pattern of living and working, but we are only now beginning to appreciate the problems of safety, urban congestion, nervous tension and atmospheric pollution which have accompanied its development. In the same way, the development of the aircraft industry outran our knowledge of how to meet the environmental needs of the human beings it intended to transport through the skies."

The scientists, save for the geneticists, were all person who had actively participated in the past in the efforts to reduce industrial toxicological hazards, air pollution, stream and harbor pollution, and soil and crop pollution, and de-

struction which has occurred with developing industries largely uncontrolled until serious damage had already taken place. They are determined that with a much greater body of knowledge to draw on concerning radiation effects, similar situations will not arise as a result of the rapidly growing atomic energy industry with its even greater potential dangers.

Consequently, once they had assured themselves on two points, namely: weapons testing at the present rate and with present safeguards was not a present menace, and the safety precautions of our present atomic energy operations were indeed effective, they became preoccupied with pointing out the problems inherent in a greatly expanded atomic energy industry. There constantly recurs through the report the idea that all is well today but for the future let us be very careful indeed.

In summary, the report was totally reassuring as regards nuclear weapons testing, it did not attempt to face up to the problems of an atomic war, and finally it was preoccupied with the potential hazards inherent in a developing era of large scale atomic power.

Summary Report of the Committee on Genetic Effects

This Committee consisted of geneticists, one authority on radiation pathology, one authority on radiological physics and radiation hazard control, and a mathematician, Dr. Warren Weaver of the Rockefeller Foundation, who chaired the group.

They considered the genetic effects against the background of present knowledge concerning radiation as a cause of mutations in microorganisms, plants, insects, and mice, bearing in mind the tendency of modern civilization to conserve all human life whether perfect or imperfect. They call attention to the perhaps greater importance of mutations which are relatively inapparent such as defects in resistance to disease processes, decreased fertility and curtailed life span, and impaired physical and mental vigor. The more dramatic mutations, monsters, still births, and early developmental defects leading to abortion and miscarriage are not apt to be passed on to another generation. The apparently relatively negative results of the genetics survey of the survivors' first generation at Hiroshima and Nagasaki serve to emphasize the validity of this point of view. This study demonstrated that with the methods used and the radiation dosages received, the heavily irradiated surviving population was not sufficiently large for it to be possible to demonstrate a statistically significant difference in the number of mutations in the offsprings of irradiated parents as compared with offsprings of non-irradiated control parents. It did not prove in any sense of the word that there was no genetic effect.

Following a general discussion of the mechanisms of genetic change especially as produced by radiation, both natural and artificial, the committee made certain recommendations. In doing so they used natural background radiation exposure (i. e., radiation from cosmic rays, igneous rocks, radium and radiopotassium in our bodies, etc.), and the so-called spontaneous mutation rate as base lines. In addition they were unanimous that no increase in the spontaneous mutations rate was desirable and that all radiation exposure to the germ cells at whatever rate of exposure did indeed increase the mutation rate in proportion to the total exposure received at the time of conception. Consequently they stated that all radiation exposure to the gonads was detrimental and consequently radiation exposures should be kept at the minimum consistent with the overall needs of a society.

They then observed that half of the American children were born of parents approximately 80 years of age or less. They noted that by the age of 30 the average American would receive germ cell exposures as follows:

1. Background or natural radioactivity ---------------------------------- 4.3r
2. Medical X-rays --
3. Fallout from weapons testing if continued at rate for the past 5 years -- 0.1r (0.02 to 0.5r)

They then estimated that the exposure necessary to double the mutations rate in humans lay between 52 and 150r, more likely 30r to 80r, but also that different gene loci were quite different in their sensivity to radiation. Taking these observations into consideration they felt that if the population as a whole were to receive no more than 10r man-made exposure to radiation to the germ cells prior to the age of thirty no serious consequences would result. They, therefore, recommended that no one should receive a total accumulated dose to the repro-

duction cells of more than 50r prior to the age of thirty without clear cut medical reasons, and that in any event the average exposure of populations as a whole should not exceed 10r by the age of thirty. They point out that at present about ⅛ this figure is already being used up by medical x-ray exposures many of which could with proper precautions be greatly reduced.

As to occupational exposures the Committee considered this to be a limited group—no estimates were made as to its actual or potential size.

As finalized in the report the recommendations are:

1. There should be a national system of keeping radiation exposures on all persons as is now practiced at AEC establishments.
2. Medical exposures to the germ cells should be reduced.
3. No more than 10r by age thirty for the population as a whole.
4. The subject should be reviewed periodically with a view to possible further reduction in exposure.
5. No body, however, employed, should receive more than 50r of exposure prior to the age of 30.
6. For special activities inherent in which are a greater liability to over-exposure individuals who for one reason or other are unlikely to procreate should be selected.
7. The state of knowledge in the field of genetics has been outrun by our knowledge in the field of physics.
8. Keep all exposures to the germ cells as low as possible for radiation exposure is generally detrimental to living cells.

In essence, this Committee formalized the current thinking on the subject. It did not come up with any new or startling conclusions or recommendations.

The Committee on Pathologic Effects of Atomic Radiation

This Committee was composed of scientists well versed in radiation pathology and chaired by Dr. Shields Warren, Director of the Cancer Research Institute of the New England Deaconess Hospital, Boston, Massachusetts, and was for five years—1948 to 1952—Director of the Division of Biology and Medicine of the Atomic Energy Commission.

This group and subcommittees on blood, lung, delayed effects, and toxicity of ingested radioactive materials reviewed the present state of knowledge and found that our knowledge of immediate effects was much greater than for delayed effects. They observed a five year lessened life span for American radiologists, estimated to have received from a few roentgens to 1000r of exposure as compared with physicians not using radiation—and agreed that until we had more precise knowledge of the cumulative effects of repeated small exposure of the whole body to radiation the rule of thumb recommended by the Genetics Committee could equally well apply to medical effects. That is, no one should receive more than 50r total accumulated dose to the reproductive cells by age 30—and no more than 50r for each decade thereafter. This, they felt, would assure that any life expectancy curtailment would be exceedingly minor, and the likelihood of induced leukemia minimal. They noted that as far as effects on the blood-forming organs, the intestinal tract, etc., are concerned, none of these effects have been detected among those who have adhered to present permissible dose levels.

As for the hazards from ingestion and radioactive materials, they confirmed the validity of existing National Committee for Radiation Protection and International Commission for Radiation Protection recommendations and as for the most important of the fission products in fallout, namely Strontium-90 they stated "there seems to be no reason to hesitate to allow a universal human strontium burden of 1/10 of the permissible yielding 20 rep in a lifetime. * * * Visible changes in the skeleton have been reported only after hundreds of rep were accumulated and tumors only after 1,500 or more." The permissible level referred to is that recommended by the NCRP for industrial workers. The Committee noted that although "some children have accumulated a measurable amount of radioactive strontium in their bodies, the amount is quite small—a thousandth of what is considered a permissible dose. The Committee concluded, "then, that Strontium-90 is not a current threat, but if there were any substantial increase in the rate of contamination in the atmosphere, it could become one."

Committee on Meteorological Aspects of Atomic Radiation, Chairman Harry Wexler, U. S. Weather Bureau

In this part of the report there is the fullest discussion of fallout from nuclear weapons. They distinguish between kiloton bursts when the cloud does not penetrate to the stratosphere and megaton bursts where the cloud does. They estimate that with surface bursts, i. e., where the fireball touches the ground 70–80% of the residual radioactivity falls out nearby, i. e., with small weapons a few miles, with larger ones up to 300 miles or more. They emphasize the ease of predicting this "nearby" fallout pattern after the fact and the problem of predicting its precise pattern prior to detonation.

They speak of intermediate fallout, i. e., material of small particle size released below the stratosphere and some 80% of which falls out within three weeks in the same hemisphere in which it originated and tending to uneven distribution associated with rainfall and wind patterns along a broad band in the same general latitude as that of its origin. Finally, they refer to delayed fallout of material which has gained entry into the stratosphere. It is slow with an average storage time in the stratosphere of 10 years, plus or minus 5 years. This delayed fallout tends to distribute itself more or less uniformly over the surface of the earth over the years.

They state that "at present, the amount of Sr 90 in the stratosphere from nuclear weapons tests is far too small to approach maximum permissible concentration even if it were all deposited now." They urged a continuing program to check on the amount of radioactivity in the stratosphere as necessary so that if there were to be a greatly increased rate of thermonuclear weapons testing activities we would know at the earliest moment when it was time to slow down in terms of potential hazard from Sr 90 to man.

There is also a discussion of the radioactivity from fallout of the intermediate and delayed variety. They point out that it is usually too feeble to measure with a hand monitor—that air sampling does not give precise results as the amount of the passing air does not bear a direct relationship to what falls on the ground. The best measure of the actual fallout available to date are laboratory analysis of fallout on gummed paper, in collecting pots, and actual analysis of the soil.

There is a discussion of atmospheric radiocontamination as a result of uncontrolled release of materials such as radio-krypton and radioiodine from power reactors and processing plants. They point out that continued control over release of these products as is now done is essential. Control is by permitting a "cooling" time for short-lived radioactive materials to decay away, by off-gas cleaning, and by scheduling release of materials with due regard to meteorological conditions at the time.

There is a section on possible uses of radioactive materials in the study of the science of meteorology. Natural radon gas in the air can be helpful in understanding vertical movements of air from the land. Weapons tests have taught much with respect to lateral spread of air masses at various altitudes—how rain scavenges the atmosphere of particles—the rate of transport from the stratosphere to the troposphere and the removal time for water from the atmosphere. Experiments could be conducted using introduced radioactive materials under controlled conditions to study airflow and diffusion rates, hydrometeorology, i. e., condensation, precipitation and avaporation, and to study electricity of the atmosphere especially the possible relationship of electrical fields to the weather.

As to effects of nuclear weapons testing on the weather the committee stated:

1. Nuclear Weapon debris was not effective as a seeder for rain.
2. The amount of ionization produced is insignificant in meteorological terms.
3. There has been no measurable decrease in the amount of direct sunlight reaching the earth whereas volcanoes have been known to decrease it by as much as 10–20% for appreciable periods of time.
4. The apparent recent increase in severe storms is probably the result of "improved methods of reporting."

Committee on the Effects of Atomic Radiation, Oceanography and Fisheries, Chairman Roger Revelle, Scripps Institute of Oceanography

This group viewed the past record of this country with respect to pollution of streams, waterways and harbors with extreme repugnance. They point out

that 71% of the earth's surface is ocean and that eventually everything gets into the oceans.

They note that the sea as compared to the land is relatively nonradioactive. Natural radioactivity of the seas is 1/100 that of igneous rocks. As a result of weapons tests they report the following: two days after Operation Castle was over in the spring of 1954 there was a millionfold increase in radioactivity of the surface waters near Bikini; that after four months 1500 miles away it was three times the normal amount and that at 13 months are area of surface water contamination had spread over a million square miles, and that at a distance of 3500 miles from Bikini the "artificial" radiactivity was ⅕ the natural.

They concluded that to date there has probably been no damage to life in the sea except that at the test site proper. They call attention to concentration of radioactivity by plant forms in the sea and warn repeatedly against indiscriminate dumping of radioactive wastes into the sea. They discuss the "flushing time" of the Black Sea 2500 years as compared with perhaps 100 or 200 years for the shelf-deeps of the Atlantic and Caribbean. They stress they need to know much more about the ocean depths and their movements. (The International Geophysical Year has a very large-scale study of the depths planned for 1957–58.) This committee would apparently permit "controlled" sea disposal especially of short-lived radioactive materials. They recommend that "Industrial agencies formulate conventions for the safe disposal of atomic wastes at sea, based on existing knowledge." This would seem to be a very logical and necessary move. To date, except for small amounts of short-lived material, the U. S. has not dumped any radioactive wastes in the sea. We are still storing all process wastes in tanks.

They further recommend collaborative studies of the oceans and their organisms and though a beginning has been made urge a greater effort. Finally, they contend that in ten or twenty years certain radiatracer experiments will not be possible because of widespread low level contamination of the seas. This may well be true.

Committee on the Effects of Atomic Radiation on Agriculture and Food Supplies, Chairman Prof. A. G. Norman, University of Michigan, Ann Arbor, Mich.

This group first discussed the application of atomic energy techniques to the agricultural sciences. They feel great advances will be forthcoming, but perhaps not as soon as some claim. They note the value of radioactive tracer studies in improving our knowledge of how most economically to apply fertilizers, and to improve plant nutrition. They note the great potential value of ionizing radiation to induce mutations in speeding up crop improvement programs. They point up the invaluable contribution tracer studies can make to our understanding of animal nutrition. They touched on the problem of radioisotopes as possible contaminants in food products and point out that present law classes radioisotopes of any sort or in any amount as poisons. They urge a more realistic approach to this inasmuch as no food product is or ever has been literally free of radioactivity.

There is a general discussion of possible effects of fallout and the like on the ecology of the country. The committee recommends that it may well be in the public interest to expand the present programs to a continuous study of the changes in levels of background radiation and the movements of radioactivity in the system. (This is in essence an activity that the AEC has already underway and is expanding very much along the lines recommended.)

Finally, there is a statement concerning use of radiation for food processing. They note that relatively low exposure will destroy parasites in meat and inhibit sprouting in potatoes and onions. They also note that for sterilization extremely large doses are required (millions of roentgens). They felt this area of development was moving as rapidly as warranted and that the interest of the consumer will be adequately protected. They expect at a later date to review the evidence for wholesomeness and acceptability of irradiated foods.

Committee on Disposal and Dispersal of Radioactive Wastes, Chairman Abel Wolman, Johns Hopkins University

This group considered the magnitude of the problem not as it is today but as it will become with full scale production of power by nuclear reactors. They note that to date essentially none of these wastes has been returned to the environment. It is being stored in tanks. They point out the importance of developing

more economic methods of handling these wastes to the total development of atomic power. They have no quarrel with present practices but are concerned at the future magnitude of the problem. They estimate that by 1980 there will be 20×10^7 gallons of wastes to deal with. These must, they say, be contained in some form or other. AEC has a large program to cope with this problem on two fronts—one, to produce perhaps by sintering a non-leachable stable mass and, two, to remove by separation the worst offenders, Sr^{90} and $Cesium^{137}$.

They note present practices with regard to radioisotope production, transportation and utilization are sound, but suggest review from time to time as this very rapidly expanding activity cotninues.

The discussion of reactor accidents as a hazard is quite general. They urge continued requirement of containment of the reactor itself for all but small research reactors as practiced today in this country. They urge constant vigilance and conclude that the extreme hazard—total vaporization of a reactor—is unlikely.

In other words, this entire study adds up to reassurance for the present, and repeated urgings to keep vigilant lest this new technology needlessly get out of hand.

Enclosure 2

Critique of British Medical Research Council, the Hazards to Man of Nuclear and Allied Radiation

A Report to the British Medical Research Council

The British Medical Research Council is a governmental body and was directed by the Prime Minister on 29 March 1955 to appoint a committee under the chairmanship of Sir Harold Himsworth to review the existing scientific evidence on the medical aspects of nuclear and allied radiation.

This report consists of eight chapters. The first four chapters deal with basic understandings of radiation and its biological effects, the fifth chapter with existing and foreseeable exposures due both to peacetime uses of atomic energy as well as to nuclear detonations in testing and in warfare, the sixth part with recommendations of permissible exposure and the seventh and eighth parts with summaries and conclusions.

Chapter I is an introduction to the report.

Chapter II discusses in simple terms the nature of radiation and its action on living cells. It deals with well known units, methods of measurement and biological effects.

Chapter III discusses the effects of radiation on the health of the individual. It includes discussions of the early effects upon the Japanese at Hiroshima and Nagasaki and the later development of an increased incidence of leukemia among the survivors. The British state they have demonstrated an increased incidence of leukemia in patients with arthritis of the spine treated with x-rays. They cite also American statistics on the increased evidence of leukemia in radiologists. They conclude that radiations can induce leukemia but do not quantitate the expose necessary for such an effect short of large single doses as at Hiroshima and Nagasaki.

There follows a discussion of radiation as an inducer of cancer and a conjecture that 1000r exposure to radon gas and its daughter produces induced lung cancer in the Schoneberg and Joachimsthal mines. Paradoxically, they go on to say that there is no evidence that external x- or gamma rays can cause lung tumors in man.

There is a discussion of radiation as a cause of bone tumors drawn principally from the reports of cancer of bones in radium dial workers and individuals given radium therapeutically. Most of this is American data. They feel there is not much of a factor of safety in the present maximum permissible concentration for radium. They indicate the risk of development of bone cancer from x-ray or gamma exposure in industry is insignificant. There is brief mention of skin cancer as induced by radiation, and thyroid gland cancer. Again the likelihood of this sort of thing from industrial exposure under modern controlled conditions is insignificant except, of course, in the event of accidental overexposure.

Radiation cataracts are mentioned as a hazard subject to ready control.

This report seems to understate effects of radiation on life span which has been so clearly proved in experiments with animals at, to be sure, radiation doses somewhat above permissible levels. The National Academy of Sciences report emphasizes this effect and cites the reduced life expectancy of American radiologists.

Both reports mention effects of radiation on developing fetuses, and the temporary sterility in males exposed to a few hundred roentgens at a single exposure. The British report is totally reassuring on the effects of occupational exposures on fertility.

Chapter IV is a very lengthy genetics effects discussion with many figures, tables and calculations and a critique of the Atomic Bomb Casualty Commission genetics stud: in Japan. This is a highly technical discussion and comes out with the same conclusions as does the National Academy of Sciences, namely that a dose of radiation which would double the mutation rate of a relatively small group of prospective parents would produce no noticeable effects. "For levels of radiation up to the doubling dose, and even some way beyond, the genetics effects of radiation are only appreciable when reckoned over the population as a whole and need cause no alarm to the individual on his own account."

Chapter V discusses natural radioactivity—radiation from appurtenances of civilization and occupational exposure to radiation. The report concludes that diagnostic medical X-rays produce exposures to the germ cells of the order of 22 percent that of background and constitute the most important source of man made irradiation. It is estimated that the United Kingdom Atomic Energy Authority's employees receive an average of 0.4 r per year.

The estimated external radiation exposure to people in Great Britain from fallout from all past nuclear tests has been quite minimal. "* * * Including all ordinary atomic bombs exploded before December 1955, and calculating all the radioactivity which they have contributed and will contribute over the next 50 years, it is found that the total dose which a man, continuously out of doors, night and day, would receive is 0.005 r. To this dose from ordinary atomic bombs must be added the dose of thermonuclear weapons. For these latter the dose from the radioactivity still to be deposited is more important. It can be estimated that the accumulated dose from thrmonuclear weapons is 0.002 to 0.003 r with another 0.027 r still to come. All these doses together add up to about 0.035 r from weapons already exploded. This is a maximum dose. The loss of radioactivity from weathering has not been taken into account, nor has the protection afforded by buildings in and around which most people in this country spend a large part of their lives. It would be realistic to divide the dose by three for weathering and by seven for protection afforded as a result of time spent in houses. The average inhabitant of this country may therefore receive in the next 50 years between 0.001 and 0.002 r from this fallout, or 0.02 to 0.04 percent of the radiation that he will receive during the same period from natural surroundings."

The report has this to say about the effects of a continuing program of testing: "* * * if the firing of both types of bomb were to continue indefinitely at the same rate as over the past few years, there would be a buildup of activity gradually reaching a plateau in about a hundred years time which, on the same basis of calculation, would give the average individual a dose over a period of 30 years of 0.026 r or about 0.9 percent of what he would receive in the same period from natural sources."

An important radioactive component of fallout material is Strontium-90. This isotope may be deposited in the bone and when present in sufficient quantities can cause bone cancer. The United Kingdom Medical Research Council report estimates that to date about 0.011 curies of Strontium-90 per square mile has fallen and that future deposits from past tests may produce a maximum of 0.045 curies of strontium-90 per square mile by 1965. These data are immediately evaluated in the report, "* * * these figures should be viewed against the background of the fact that the top one foot of soil has always contained on the average about one curie per square mile of the equally, if not more, dangerous naturally occurring radium."

They estimate the hazard from plutonium in fallout as very small. They feel Cesium 137, Iodine 131 and Barium 140 are of very little significance outside a nearby area of very heavy contamination. They estimate the gonadal dose as 1 percent of natural background and diagnostic radiology as 22 percent. The discussion of atomic warfare is too scant to consider here.

Chapter VI, Assessment of the Hazards of Exposure to Radiation, is in essence a summary of the foregoing—pointing out the differences between effects on the individual and genetic effects. They conjecture that no "authoritative recommendation will name a figure for permissible radiation dose to the whole population additional to that received from natural sources, which is more than twice that of the general value for natural background radiation." This is

estimated by the British at 0.1 r per year, hence 3 r in 30 years and 7 r in 70 years. The National Academy of Sciences estimate is an average 4.3 r in 30 years from natural background exposure and they recommend 10 r as the top figure for average exposure of the population as a whole before age 30.

As to the hazard from strontium^{90} the report states "if the concentration in human bones showed signs of rising greatly beyond one-hundredth of that corresponding to the maximum permissible occupational level" they would feel that immediate consideration were required. This figure is 10 times the highest they report in man today. The National Academy of Sciences report states "It appears, then, that strontium^{90} is not a current threat, but if there were any substantial increase in the rate of contamination of the atmosphere, it could become one."

The conclusions are to all intents and purposes identical to those of the National Academy of Sciences report.

1. Adequate justification should be required for the employment of any source of ionizing radiation on however small a scale. This is not explicitly stated in the National Academy of Sciences report but is inherent in it.

2. Dose levels to the individual—0.3 r per week—200 r in a lifetime for occupational exposures and no more than 50 r the first 30 years of life.

3. No more than twice natural background from man made sources for the population as a whole.

4. The present and foreseeable hazards from external radiation due to fallout at present rate of testing is insignificant. As to internal hazards from strontium^{90} at its present level no detectable increase in the incidence of ill-effects is to be expected. "Nevertheless, recognizing all the inadequacy of our present knowledge, we cannot ignore the possibility, that if the rate of firing increases and particularly if greater numbers of thermonuclear weapons are used, we could within the lifetime of some now living, be approaching levels at which ill-effects might be produced in a small number of the population." This is a rather roundabout way of saying, "let's be careful."

5. a. All sources of radiation should be under close inspection. A personal record not only of doses of radiation received during occupation but also of exposures from all other sources such as medical diagnostic radiology should be kept for all persons whose occupation exposes them to additional sources of radiation. The National Academy of Sciences report would seem to include the whole population in its similar recommendations.

b. Present practices in medical diagnostic radiology should be reviewed with the object of clarifying the indications for different special types of examination now being carried out and defining more closely, both in relation to the patient and to the operators, the conditions which should be observed in their performance. This says, in effect, "let's tighten up on unnecessary exposures."

c. The uses of radiotherapy in non-malignant conditions should be critically examined—again, a warning to tighten up on unnecessary exposures.

d. The small amouts of irradiation from miscellaneous sources, such as x-ray machines used for shoe fitting, luminous watches and clocks, and television apparatus should be reduced as far as possible.

6. They end with a plea for better vital statistics. No comparable recommendation appears in the National Academy of Sciences report.

(Enclosure 3)

Comments on "Race Poisoning by Radiation"

By H. J. Muller

Professor Muller's remarks in regard to mutation changes resulting from nuclear warfare are in conformity with generally held views of geneticists. It is noted that Dr. Muller is a member of the National Academy of Sciences Study Committee on Genetics and the report issued by the Committee was unanimous.

With regard to the peacetime use of nuclear energy, Professor Muller presented estimates of life shortening based on two assumptions, i. e., that an atomic energy worker would receive the maximum permissible exposure every week for a 40 year working period and that the life shortening would be proportional to the total radiation dosage received. As indicated in Professor Muller's article and by figures released by the Atomic Energy Commission, the exposures to atomic energy workers have been considerably less than the maximum permissible amounts ("relatively few workers receive more than a fifth of this amount").

The possible effect of life shortening was considered by the Committee on Pathologic Effects of the National Academy of Sciences study on the biological effects of radiation. The Committee made the following statements:

"The shortening of life correlates roughly with dose of radiation, but has not yet been demonstrated at low doses."

"As the permissible dose level which they (Genetics Committee of the N. A. S.) have hypothesized as desirable for large populations were to be applied there would be no demonstrable somatic effect, although a theoretical minor shortening of life span could not be ruled out."

We are in complete agreement with Professor Muller's remarks that atomic energy "operations must be carried on with such rigorous safeguards that those working on the projects will feel no fear for themselves or their descendants."

In this connection, the AEC may consider placing an upper limit of yearly exposure for atomic energy workers. The average exposure to atomic energy workers during past operations, however, has been so far below the maximum permissible level that the placing of a yearly upper limit would not be expected to impose any major restrictions.

UNITED STATES SENATE,
COMMITTEE ON ARMED SERVICES,
January 31, 1957.

Hon. LEWIS L. STRAUSS,
Chairman, United States Atomic Energy Commission,
19th and Constitution Avenue, Washington 25, D. C.

DEAR ADMIRAL STRAUSS: Attached for your information is copy of letter just received which, as you will see, is signed by five professors of Yale University. The points brought out in this letter are to me extremely important, and coming from the source they do, I feel deserve most careful attention by the officials of our Government, particularly those working with and deciding the policy on development of nuclear weapons.

With kind regards, I am

Sincerely yours,

PRESCOTT BUSH,
United States Senate.

Enclosure.

JANUARY 21, 1957.

The Honorable Senator PRESCOTT BUSH,
United States Senate,
Washington, D. C.

DEAR SENATOR BUSH: At your request we are sending you an outline of the conversation you had with the members of the Yale Department of Biophysics in Woodbridge Hall on December 18th, 1956 on the subject of radiation hazards. The discussion covered the following points which we wished to emphasize to you.

1. The effects produced by nuclear weapons are world-wide. The radiation from our tests will not only be felt elsewhere, but similar weapons tested in Russia, England, or Australia will produce effects in our country as well as their own. The radiation effects are world-wide because most of the radioactivity is carried up into the stratosphere where it remains for such a long time (around ten years) that it becomes distributed over the whole world before the radioactive particles fall to earth or decay.

2. The effects produced by radiation are not reversible. If we were to find, ten years from now, that the people of this country had received too much radiation, we would be at an impasse because the residual effects would already have been produced. If we were to find that the population of this country, or of any country, or of the world for that matter, had received too much radiation, it would be too late to do anything about it. It seems clear that the present rate of world-wide weapons testing is bound to increase and therefore any margin of safety based upon our present rate of testing is sure to be wrong.

3. The effects of radiation are not completely understood. At the present time one of the big areas of disagreement among scientists is on the amount of strontium 90 (one of the radioactive elements produced only in the nuclear weapons tests) which should be permitted to accumulate in the world. Everyone's calculations of the amount of strontium 90 now at large are based on the AEC's data as presented by Commissioner Libby. The disagreement is on how much strontium 90 the human body is able to tolerate. In the twenty years since levels were set up for the maximum amount of radiation to which people

should be exposed, tolerance levels have been revised downward periodically and drastically. For example, the following table indicates the steady downward trend:

Estimated permissible level for occupational risk (in milliroentgens per week)

Year:	
1930	1,000
1936	500
1949	300
1956	100

We feel that there is a good chance that the tolerance levels will be still further revised downward in the future, as it has been in the past. If this were to happen, we certainly shall find ourselves in the tragic situation of having already exposed our population to radiation levels higher than those considered safe.

4. Because radiation effects seems to be cumulative, we may end up by exposing the population of this country to so much radiation from medical x-rays and nuclear weapons testing that we have no safety margin for radiation produced by nuclear power plants. At the present moment, the people of this country receive more radiation through medical x-rays (which of course are usually justified medically) than most of the other countries of the world. We, therefore, would be the first to suffer from the effects of nuclear weapons testing.

5. Because of the points mentioned above, we feel that the decision as to the extent of nuclear weapon testing should be made by a larger group of people than is at present making this decision. Obviously involved in the whole matter of weapons testing is the relative importance of the radiation danger about which we have spoken versus the useful information to be gathered for defense purposes. We do not advocate prohibition of nuclear weapons testing, but we do wish to see discussed the important point of the possible danger from such tests because we feel that the danger is real and that the people should not be misled about what is involved.

Yours sincerely,

(Signed:) ERNEST C. POLLARD,
Chairman, Biophysics Department.
RICHARD B. SETLOW,
Associate Professor Biophysics.
FRANKLIN HUTCHINSON,
Assistant Professor Biophysics.
WALTER R. GUILD,
Assistant Professor Biophysics.
HAROLD J. MOROWITZ,
Assistant Professor Biophysics.

APR 6, 1957.

Hon. PRESCOTT BUSH,
United States Senate

DEAR SENATOR BUSH: I am writing in response to your letter of January 31, 1957 forwarding a copy of a letter of January 21, 1957, signed by five members of the Yale University Department of Biophysics: Ernest C. Pollard, Richard B. Setlow, Franklin Hutchinson, Walter R. Guild and Harold J. Morowicz. I appreciate your patience in permitting the staff to take the necesary time to study the issues presented by the authors which as you know involve broad national defense policy and highly technical genetical and biophysical considerations. As was pointed out in the interim acknowledgment of the General Manager of March 13, 1957 and in earlier telephone discussions with your staff, the questions raised required the participation of several AEC divisions in the preparation of the final reply.

The letter of Professor Pollard and his colleagues, as is to be expected from their scientific standing and their familiarity with certain aspects of the problem, displays a high degree of appreciation of some of the factors involved in the limitation of human exposure to radiation from nuclear weapons test programs and from other sources. These and other factors upon which decisions regarding our various programs must be based are not only under constant study by members of our staff and by our consultants, but those factors involving biological effects of radiation and the exposure of persons to radioactive fallout from weapons tests are the subject of a substantial portion of our research programs in the fields of biology and medicine.

Our staff is in general agreement with the basic scientific statements made in the letter described by the authors as an outline of their conversaion with you on December 18, 1956. Because of the complexity of the subject, a brief summary of the considerations involved cannot be very definitive. I regret that we do not have available for comment a more complete statement of the authors' views.

I have asked our Division of Biology and Medicine to make an analysis of the various points briefly expressed in the letter in the light of our current thinking on problems of radiation protection. I believe you will be interested in their report, copies of which I enclose.

My own comments on specific statements contained in the letter are limited to a consideration of paragraph 5, which appears to summarize the conclusions of the authors, and which reads,

"Because of the points mentioned above, we feel that the decision as to the extent of nuclear weapon testing should be made by a larger group of people than is at present making this decision. *Obviously involved in the whole matter of weapons testing is the relative importance of the radiation danger about which we have spoken versus the useful information to be gathered for defense purposes.* We do not advocate prohibition of nuclear weapons testing, but we do wish to see discussed the important point of the possible danger from such tests because we feel that the danger is real and that the people should not be misled about what is involved."

I have underlined one sentence of paragraph 5 to emphasize that a basic consideration in decisons involving weapons testing is the relationship of the test programs to our national welfare. While the Atomic Energy Commission has certain responsibilities for the development and production of nuclear weapons appropriate to the estimated military needs of the nation, there are involved here, as you are of course aware, questions of national policy which extend far beyond the specific responsibilities of the Commission.

In the quoted paragraph above, the authors refer to "useful information to be gathered for defense purposes." Knowledge gained from past weapons tests have made it possible for us to increase reliability and safety, to improve the yield of explosive devices while reducing the amounts of material used, and to provide us weapons capable of being used tactically. One of the principal objectives of recent tests has been to develop weapons which may be used in defense against attacks and to reduce the radioactive fallout from weapons. As has been announced, the most recent weapons test series in the Pacific was planned and carried out with yields of explosive forces much less than those of the 1954 series.

In reaching decisions to recommend test programs for the approval of the President, the Atomic Energy Commission and the Department of Defense attempt to take advantage of all available information. The number of persons who can participate in the total of all of the considerations involved is necessarily limited. On those facets of the problem which do permit wider participation, we have sought and received counsel from many sources. In addition to persons with whom we have formal relationships of one kind or another, there is constant give and take with a great number of scientists and other professional persons here and abroad.

The total of our contacts represents, we believe, a good cross section of informed opinion throughout the world.

We share the author's view that possible dangers from weapons tests should be discussed and that the people should not be misled about what is involved in exposure to radiation from weapons tests or from peaceful uses of nuclear energy. The potential hazards should neither be minimized nor exaggerated. We believe that the extensive data which have been collected, particularly in programs sponsored by the United States and by the United Kingdom, demonstrate that the degree of potential hazard to the public is very low.

Much of the pertinent information is summarized in reports published last year on studies made concurrently but independently by the National Academy of Sciences and by the British Medical Research Council. Copies of these reports are enclosed for your convenient reference.

I hope that you will find the information which we are submitting helpful. If I can be of further aid to you, by arranging for discussions with appropriate Commission personnel or by other means, please call on me.

Sincerely yours,

W. F. LIBBY, *Acting Chairman.*

Reports of National Academy of Sciences and British Medical Research Council.

REPORT ON QUESTIONS RAISED BY YALE DEPARTMENT OF BIOPHYSICS IN LETTER TO SENATOR PRESCOTT BUSH DECEMBER 18, 1956

Prepared by Division of Biology and Medicine
U. S. Atomic Energy Commission March 27, 1957

The following report discusses a letter from members of the Department of Biophysics, Yale University, to Senator Prescott Bush, January 21, 1957. The letter is signed by Ernest C. Pollard, Richard B. Setlow, Franklin Hutchinson, Walter R. Guild, and Harold J. Morowitz. The letter was transmitted by Senator Bush January 31, 1957, with the following note:

"Attached for your information is copy of letter just received which, as you will see, is signed by five professors of Yale University. The points brought out in this letter are to me extremely important, and coming from the source they do, I feel deserve most careful attention by the officials of our Government, particularly those working with and deciding the policy on development of nuclear weapons."

The letter is described by the authors as an outline of a conversation on the subject of radiation hazards between Senator Bush and members of the Yale Department of Biophysics, December 18, 1956. The letter includes five numbered paragraphs, each of which discusses a point introduced by the initial sentence. For convenience in the following discussion, reference to each of these paragraphs is by number, with the point stated first, followed by our comment.

Because our comments may appear to be rather critical, we wish to state in advance that the letter is unusually well written considering the brevity with which the authors attempted to express their ideas. Thoughtful treatment of the subject is, of course, to be expected from a group of such competence and professional standing. The comments are as follows:

Paragraph 1. The paragraph is limited to factual statements on which there is general agreement.

Paragraph 2. "The effects of radiation are not reversible." The authors apparently have in mind some very specific effects of radiation, such as genetic effects, which are generally considered to be not reversible. We do not believe that, in general, the statement can be supported. For example, the transient effects characteristic of radiation sickness are appropriately described as reversible. Whether or not those effects of exposure of an individual to radiation which may, but not necessarily do, result in leukemia or cancer are to be considered as reversible or not reversible may be a question of semantics. For example, if a number of persons receive equal doses of radiation and one contracts leukemia as a result, it would appear that in the case of the one person some of the effects of the radiation were not entirely reversible. It is not apparent, however, that this is necessarily true in the cases of those who failed to contract the disease.

"If we were to find, ten years from now, that the people of this country * * * or of any country, or of the world * * * had received too much radiation, it would be too late to do anything about it." This is true, of course, whether the consequences implied by "too much radiation" are extremely serious or of relatively minor import from the point of view of their total impact on the population as a whole. The nature of the biological effects of radiation is such that it is impossible to categorically divide levels of exposure to radiation into *safe* and *unsafe* values, if one uses the term *safe* in the sense of absolute freedom from risk.[1] This is because the severity of biological effects, or the probability of a serious effect, increases from very low values for low exposures to radiation to high values for high exposures to radiation.

For example, it is generally considered that any exposure to radiation, no matter how small, makes a correspondingly small contribution to the probability of genetic mutation. On page 22 of the National Academy of Science Summary Reports it is stated that "U. S. residents have, on the average, been receiving from fall-out over the past five years a dose which, if weapons testing were continued at the same rate, is estimated to produce a total 30 year dose of about one tenth of a roentgen * * *" By comparison, it is stated, p. 21, that each person in the United States receives from natural background

[1] While the word *safe* is defined as freedom from risk, it is commonly used to describe situations in which the risk is not zero but is too low to be of concern or, possibly, to be recognized.

radiation "a total accumulated dose of about 4.3 roentgens over a 30 year period" and, from medical x-rays, "on the average a total accumulated dose to the gonads which is about 3 roentgens of x-radiation during a 30 year period." The dose rate required to double the natural rate of genetic mutation, if continued over a period of many generations, is estimated, p. 24, to lie in the range of 30 roentgens to 80 roentgens. On the basis of these estimates, if weapons tests were continued at the present rate, the effect of radioactive fallout from the tests on the genetic mutation rate would be to increase it by less than 1% of its natural value. A very small fraction of the population would be affected and a much smaller fraction would be seriously affected. The risk to the average individual, and the impact on the population as a whole, would be extremely small. Yet, since some individuals might be seriously affected, we must assume that even at these low levels of exposure people are receiving "too much radiation" unless we are convinced that the probable benefit to each person outweighs the risk.

Some perspective on relative values may be obtained by observing, on the basis of estimates quoted above, that exposures to radiation from natural sources (radioactive materials naturally in the earth's crust and cosmic rays from outer space) are more than ten times as high as those estimated to result from weapons testing if continued at the present rate. These are levels of radiation in which the human race has developed and prospered. Whatever risk there may be to the individual member of the race as a result of these relatively low additional exposures, it is quite low compared to many common hazards of life.

It appears that the authors are conscious of the smallness of the risk involved at the levels of exposure under discussion, since in paragraph 4 of their letter they restate their fear in the words, "* * * we may end up by exposing the population of this country to so much radiation from medical x-rays and nuclear weapons testing that we have no safety margin for radiation produced by nuclear power plants." That they also recognize the element of balance of risk against probable benefit is reflected in the statement in paragraph 5 of their letter, to wit: "Obviously involved in the whole matter of weapons testing is the relative importance of the radiation danger about which we have spoken versus the useful information to be gathered for defense purposes."

Summarizing our discussion of paragraph 2, it appears that whether or not ten years from now the population will have received too much radiation as a result of weapons tests will depend not only on the number of persons who may have suffered as a consequence of our weapons tests but also upon the number who may have been enabled to avoid suffering as a result of the contributions of the tests to our defense efforts.

Paragraph 3. "The effects of radiation are not completely understood." It would, perhaps, be more appropriate to say that the processes of life are not completely understood. We probably know more about the biological effects of radiation than those of any other element in our environment; certainly more than we know about the effects of many drugs and organic chemicals developed during the past few years, and perhaps more than about such factors as psychological stress, diet, exercise, etc.

"At the present time one of the big areas of disagreement among scientists is on the amount of strontium 90 * * * which should be permitted to accumulate in the world. Everyone's calculations of the amount of strontium 90 now at large are based on the AEC's data as presented by Commissioner Libby. The disagreement is on how much strontium 90 the human body is able to tolerate." The AEC has been supporting a broad program of investigation of strontium 90 in the atmosphere, soils, plants, animals and humans for more than three years. Most of the investigators are employees of other government agencies, universities, hospitals, etc. A similar program has been under way in the United Kingdom for about the same length of time, and other countries are undertaking studies of this kind. The best data available on the human content of strontium 90 is that in the report, "Strontium 90 in Man" by J. L. Kulp, W. R. Eckelmann, and A. R. Schulert of Columbia University, published in *Science*, February 8, 1957. The skeletal concentrations observed by Kulp, et al, are generally less than 0.01 of those considered acceptable in general population groups by such scientific groups as the International Commission on Radiological Protection, the National Academy of Sciences, and the Medical Research Council of the United Kingdom.

We believe that the principal area of disagreement between scientists well informed in this field is not on how much strontium 90 the body can tolerate,

in the usual sense of the word, but whether or not there may be a very small probability that a low concentration of strontium 90 in the skeleton of an individual will result in bone cancer. There is no experience of production of bone cancers in humans by strontium 90. Experience in humans is limited to the effects of radium as, for example, in the case of the luminizing industry. Estimates of the effects of strontium 90 to be expected in humans are based on comparative studies of strontium 90 and radium in animals and comparative studies of radium in animals and humans. Because bone cancers occur normally in animals (and in humans), and because cancers induced by radioactive materiels cannot be distinguished from those which occur from other causes, the relationship between concentrations of strontium 90 in the skeleton and the resultant probability of bone cancer can be determined only by conparing rates of occurrence in animals containing strontium 90 with rates of occurrence in normal animals. The increase in rate of occurrence that can be measured with confidence depends upon the numbers of animales under observation.

From studies made over the past ten years, it is estimated that from 1,000 to 10,000 times the concentrations of strontium 90 currently found in the skeletons of young humans would be required to produce a detectable increase in the normal rate of bone cancer. Some of our best informed radiobiologists are confident that somewhere below these concentrations the probability of a resulting increase in the rate of bone cancer would be zero, while others believe it possible that even at the very lowest concentrations there may exist correspondingly low probabilities of a bone cancer resulting from strontium 90. In the latter case, the situation is similar to the genetic case discussed in connection with paragraph 2. The question then becomes not how much can the human body tolerate but what is the risk at low levels of exposure in relation to the probable benefits associated with the exposure.

While informed radiobiologists disagree on the subject of whether or not relatively low concentrations of strontium 90 in the skeleton might conceivably result in small increases in the rate of occurrence of bone cancer, they generally agree that is such increases in rate do occur, they will not be large enough to be detectable, even at concentrations much higher than those currently observed. The degree to which speculation on the possibility of an increase in the rate of bone cancer too small to observe has become a matter of public concern is in striking contrast to the apathy with which the public accepts the fact that the rate of lung cancer has increased over the past 20 or 30 years by a factor of about ten.

"In the twenty years since levels were set for the maximum amount of radiation to which people should be exposed, tolerance levels have been revised downward periodically and drastically. . . . We feel that there is a good chance that the tolerance level will be still further revised downward in the future, as it has been in the past. If this were to happen, we certainly shall find ourselves in the tragic situation of having already exposed our population to radiation levels higher than those considered safe." In our discussion of paragraph 2, we have indicated that we do not consider that any level of radiation, no matter how low, can be considered absolutely "safe". If the exposure of the whole population to radiation at a certain level were to result in the premature death of one person, the result would be a tragedy. If it resulted in the death of several persons, it would be a greater tragedy. But, if one is realistic, one must admit that risk to human life is involved not only in other phases of our defense effort but, indirectly, in many decisions involving our foreign policy. In the case of radioactive fallout, the significant risk is not from weapons tests, but from the possibility of a nuclear war in which levels of radiation exposure may be higher by factors ranging upward to tens of thousands or hundreds of thousands. Obviously, this would be a much greater tragedy.

Paragraph 4. "Because radiation effects seem to be cumulative, we may end up by exposing the population of this country to so much radiation from medical x-rays and nuclear weapons testing that we have no safety margin for radiation produced by nuclear power plants." Estimates quoted in discussion of paragraph 2 indicated that at present rates of weapons testing, anticipated exposures to radiation from fallout are about one-thirtieth of current average rates from medical x-rays. At these relative magnitudes, a four percent increase in the use of medical x-rays would wipe out any gains resulting from the elimination of fallout from weapons testing. However, the relative merit of exposing persons to radiation from medical x-rays, nuclear power reactors, and fallout from weapons tests must depend upon the contribution that each may make to per-

sonal and national welfare. The primary consideration with respect to radiation from fallout is, how important to our national welfare is our nuclear weapons program?

Paragraph 5. "Because of the points mentioned above, we feel that the decision as to the extent of nuclear weapons testing should be made by a larger group of people than is at present making this decision." Decisions as to the extent to which weapons tests shall be conducted involve highly sensitive information including weapons design and capabilities, military strategy, and national policies. This limits participation in these decisions to persons officially responsible for our national security.

In evaluation of the radiological hazards associated with weapons tests for use in national planning, the Atomic Energy Commission not only seeks existing information from all available sources but supports extensive research on the production, dissemination, biological uptake, and effects of radioactive materials released by nuclear detonations. The number of persons with whom the Commission has contact on various phases of the question is very large.

"Obviously involved in the whole matter of weapons testing is the relative importance of the radiation danger about which we have spoken versus the useful information to be gathered for defense purposes." We believe this to be the primary consideration.

"We do not advocate prohibition of nuclear weapons testing, but we do wish to see discussed the important point of the possible danger from such tests because we feel that the danger is real and that the people should not be misled about what is involved." The discussions contained in reports issued last year by the National Academy of Sciences and the British Medical Research Council not only explain the possible dangers from weapons tests quite thoroughly, but present differences in the views of various radiobiologists. These reports were written by study panels composed of leading scientists in the respective countries, and it is our belief that they present a good cross section of scientific opinion on these subjects. Copies of the following reports are provided herewith for transmission to Senator Bush:

(1) National Academy of Sciences, "*The Biological Effects of Atomic Radiations, A Report to the Public.*" It is recommended that this brief, non-technical survey of the subject be read before referring to the other reports.

(2) British Medical Research Council, "*The Hazards to Man of Nuclear and Allied Radiations.*" This report has been made more readable than many scientific reports without sacrifice of technical accuracy. It is suggested that Chapter VII, pages 70 ff., summarizing the discussion, be read first. The summary statements refer to paragraphs of the text by number, facilitating the selection of portions of principal interest.

(3) National Academy of Sciences, "*The Biological Effects of Atomic Radiation, Summary Reports.*" This is a summary of individual reports by six committees. While it covers much of the same ground as the report of the British Medical Research Council, views expressed in the two reports involve some basic differences. For example, the American report considers it most probable that below certain levels of exposure to radiation, the contribution of the exposure to the probability that an individual will develop cancer or leukemia is absolutely zero; while the British report considers it likely that even at the lowest levels of exposure there are correspondingly small but real contributions to the probability that the individual will develop one of these diseases.

(4) National Academy of Sciences, "*Pathological Effects of Atomic Radiation.*" Appendix II of this report summarizes the considerations related to the irradiation of persons and populations by radioactive materials within the body.

It is desirable that the general public be as well informed as is practical on all phases of radiation hazards. We know of no information on this subject which is withheld from the public, but because of the complexity of the subject, it is difficult to transmit it comprehensively in a form or forms generally usable by individual laymen. Introduction of even the primary facts into the day-today thinking of a substantial proportion of the general public is a problem in education of which the solution may require many years.

SUMMARY

At the present time, it cannot be stated categorically that there is a level of radiation which is absolutely safe. Mainly because of genetic considerations,

there exists the possibility that some biological effect—perhaps difficult to detect—will be produced at very low doses. The degree of risk, however, would be correspondingly low.

The probability is remote that any individual would be seriously affected by low level radiation contributed by fallout from weapons tests. Unless, however, the risk is absolutely zero, a low individual probability when extrapolated to a large population will result in the statistical possibility that some members of the population may be affected. Because the risks here are very much smaller than the normal hazards of life, it is impossible to estimate the maximum number of persons who might be affected.

The dose of radiation outside the body resulting from fallout contributes about 1/30 of the dose to the population from either natural sources or from medical X-rays. Current concentrations of strontium 90 in the skeleton as a result of fallout are substantially below (about 0.01) levels considered acceptable by recognized independent scientific bodies.

The important question then is whether or not the discontinuation of weapons tests by the United States for the sole purpose of reducing the presently small risk from fallout would not be more than offset by the loss of data, vital to the national security, which weapons tests yield. In the absence of an international disarmament agreement, freezing our weapons technology at the present level may constitute a far greater risk. In such an event it becomes necessary to speak of radiation risk in terms of lethal doses to large segments of the population in the event of nuclear attack, in contrast to the present discussion which is in terms of fractions of permissible levels and statistical possibilities.

WASHINGTON, D. C., *April 25, 1957.*

Dr. ALBERT SCHWEITZER,
Lambarene Hospital, Lambarene, Gabon, French Equatorial Africa.

DEAR DR. SCHWEITZER: I am writing you as a scientist, to present data bearing on a scientific fact: The degree of hazard to humanity from radioactive fallout from nuclear weapons tests.

In the press on April 24, I read your statement from Oslo on the hazards of nuclear weapons testing, and in this way learned of your fears that the present testing program may be dangerous. Since I have spent much time during the past several years in the study of this question, I am taking the liberty of writing you. Also, since your statement was issued to news media and received wide public attention, I am making this letter public in the belief that every possible action should be taken to increase public understanding on the important question of weapons testing.

Your belief in the sanctity of life, and the dedication with which you have devoted your own life and talents to unselfish causes, have made a deep impression on the minds of persons throughout the world. Your concern over the possible effects of nuclear tests is characteristic of the humane and sensitive qualities which you always have displayed, and for which you are justly honored. Along with these qualities, I know you have the intellectual strength and integrity to seek the truth wherever it lies. It is in this spirit that I write you, believing that you will welcome whatever facts I may be able to provide regarding radioactive fallout from weapons testing.

I do not know what data you have utilized in studying this question, but I seriously doubt, from the evidence of your statement, that you have had access to the most recent information. Immediately after reading your statement, I sent you a copy of a speech which I gave recently regarding what we know from scientific studies on fallout radiation and its effects. I am enclosing with this letter a copy of a paper which I am presenting on April 26 before the American Physical Society. I hope these documents will be of use to you. They demonstrate that an intensive effort has been made to calculate on theoretical grounds, and to determine from sample collections, the actual levels of radioactivity in the soil, in water, in food products, and in human bodies as a result of weapons tests.

If you have gained the impression that United States official statements do not take into account the possible hazard from internal radiation—and I fear from your statement that you have—I hasten to assure you that this is not the case. Government statements have dealt extensively with this matter. It has likewise been considered at length in a report prepared by scores of eminent scien-

tists for the National Academy of Sciences, and in England by the British Medical Research Council, both reports appearing in June of last year.

Particularly since the summer of 1953, the Atomic Energy Commission has conducted an intensive study of worldwide fallout which has revealed most of the information now available on this subject. These studies have included analysis of soil, plants, foods and other materials from many parts of the world. The United States Government has furnished this information without reserve to the United Nations Scientific Committee on Atomic Radiation, which was established at the recommendation of the United States and which has studied data provided by other countries.

Although there are some differences in the findings of scientists in this country and abroad, there is general agreement upon the approximate magnitude of the fallout and the rate at which it is descending from the stratosphere. Perhaps there is less agreement about the magnitude of the physiological effects which can be expected to result from fallout radiation. Nevertheless, it is very generally agreed, among those who have studied the question, that the radiation exposures from fallout are very much smaller than those which would be required to produce observable effects in the population. The U. S. Government agencies have been continuously concerned with maintaining this condition of very small test radiation hazard and have never neglected study and action to reduce it.

I do not mean to say that there is no risk at all. What I should like to demonstrate to you is that the risk is extremely small compared with other risks which persons everywhere take as a normal part of their lives. At the same time, I ask you to weigh this risk against what I believe would be the far greater risk—to freedom-loving people everywhere in the world—of not maintaining our defenses against the totalitarian forces at large in the world until such time as safeguarded disarmament may be achieved. Of course, a workable, safeguarded system of international disarmament is a paramount objective of the United States Government, and one which we must work for and hope and pray will be achieved.

To go into more detail on the question of risk from worldwide radioactive fallout, there are two possible hazards. The first is the genetic hazard due to radiation of the reproductive organs by penetrating gamma radiation, and the second is the hazard due to the irradiation of the bones by assimilated strontium-90, taken up largely through food. These two possible hazards should not be confused; there is no reason to fear genetic hazard from strontium-90, since it accumulates in the bones and does not appreciably irradiate the reproductive organs.

In order to understand the degree of these hazards, it is necessary to compare the amount of radiation dosage received from fallout with the amount of radiation dosage normally received by all living things because of the natural radioactivity in the environment. In this way, it is possible to put the hazards from weapons testing into the context of normal human experience.

When this kind of comparison is made, it becomes apparent that we all carry in our bodes, and have in our surroundings, amounts of radioactivity very much larger than those derived from radioactive fallout.

Cosmic rays, which come from outer space, have their radiation effect progressively diluted as they pass through the atmosphere. Thus, a person living at an altitude of about one mile above sea level receives a dosage of cosmic rays approaching double that of a person who lives at sea level. There are other variations in the natural "background" dosages. For example, people living in certain localities of uranium or thorium mineralization will receive much more radiation than the average, and their ancestors have received these much higher doses over centuries in many parts of the world. Living in a brick house, rather than in a wooden house, will, with certain kinds of bricks in certain parts of the world, increase radiation exposure many times over that from test fallout.

The additional radiation dosages which persons receive from fallout are small compared to these natural dosages and even the variations in the natural dosages. To be specific, the dosage to new bone as in children which results from strontium-90 at present is about the same as the additional dosage which a resident at sea level would receive from cosmic rays if he moved from a beach to the top of a hill a few hundred feet high.

There is no question that excessive dosages of radioactive strontium can cause bone cancer and leukemia in animals, so we should not casually dismiss

the possibilitiy of harmful results from test fallout. However, keeping in mind that populations are exposed to natural radiations considerably greater than the fallout dosages, we can attempt to determine whether these have caused any detectable effects. We can examine, for example, whether there is any obvious increase in the rate of occurrence of bone cancer and leukemia in populations living at higher altitudes or in regions of uranium mineralization, etc.

Examination of available records does not disclose any such effects. However, vital statistics have not always been carefully kept, and further studies are being carried on under the aegis of the United Nations Committee to determine whether any such effects can be detected. One fact is apparent, however—it certainly is not our normal experience that people can appreciably increase the occurrence of these dread diseases by moving to a higher altitude or by moving from a sedimentary soil, where the uranium content is low, to an igneous or granitic surface, where the uranium content is very much higher, or by moving from a wooden to a brick or concrete house.

Another way of evaluating the possible risk from strontium-90 in fallout is through comparison with the permissible concentration of strontium-90 recommended by authoritative groups. The permissible amount of strontium-90 for atomic energy workers in the United States is about 2,000 times the present strontium-90 content of new bone in the United States resulting from fallout. (Strontium-90 concentrations in the rest of the world are generally lower than those in the United States.) Authoritative groups have recommended that, on grounds of general prudence, the permissible limit for whole populations be one-tenth of that for atomic energy workers. On this basis, the present level for new bone, that is, in children, in the United States is somewhat less than one percent of the maximum permissible concentration for the population.

Perhaps a word of explanation should be given regarding these maximum permissible concentrations. As you know, scientists do not speak of "risks" or "hazards" in the sense that the words ordinarily are used. They try to measure possibilities almost to the limits of the finite; therefore, "risk" includes the possibility of effects far beyond the range of the probable or detectable. The maximum permissible concentrations are not safety limits, rather, they indicate that at considerably larger concentrations, perhaps tenfold greater, there would be definitely detectable effects.

So far, I have been discussing principally the possible risks from radioactive strontium. Radioactive fallout includes other materials which do not accumulate inside the body, but do not emit penetrating radiation which can irriadiate the sex organs and other parts of the whole body from the outside. Such radiations can produce genetic mutations.

Again, in evaluating the possibility of genetic effects from fallout, we should try to compare it with normal experience. The external dosages from fallout, that is, those which might cause genetic effects, have averaged between one and five thousandths of one roentgen per year in the United States during the last three or four years. This figure should be compared with a normal dosage of 150 thousandths of one roentgen per year from cosmic rays and natural radioactive materials in the environment. In other words, the external fallout radiation has been from 0.7 percent to about three percent of the natural radiation exposure.

As another example, in certain countries of the world a brick house might easily have enough natural radioactive material in the walls to give up to 40 thousandths of a roentgen more exposure per year than a wooden house and a concrete block house gives about 100 thousandths of a roentgen more annually. These dosages range between 8 and 100 times the dosage due to test fallout.

Obviously, the genetic effect of fallout radiation must be very small compared with the genetic effect of natural radiation.

As you pointed out in your statement, radioactivity from tests which already have been held is present in the stratosphere, from which it will descend for years to come. The radioactivity of this material constantly is decreasing through normal radioactive decay. The tiny radioactive particles fall so slowly from the stratosphere that the continuing fallout in the United States just about compensates for the radioactive decay of the radiostrontium already deposited. Therefore, the present level of radiostrontium in the soil is about as much as we shall ever have from tests already fired.

Continued testing would not increase radioactivity on a straight additive basis, since an equilibrium would be established between the added radioactivity and radioactive decay. If tests were to continue until 1983 at the rate of the past five

years, levels in the United States would be expected to reach about four times their present values. Levels about six times the present ones would be reached by the year 2011 if testing were to continue for that long a time.

I hope that I have provided enough information to demonstrate that the risk from nuclear testing at the present rate is small. Of course, a great amount of more detailed information is available, and I shall be glad to supply it to you if you wish. No scientist contends that there is no risk. We accept risk as payment for our pleasures, our comforts, and our material progress. Here the choice seems much clearer—the terrible risk of abandoning the defense effort which is so essential under present conditions to the survival of the Free World against the small controlled risk from weapons testing.

Sincerely yours,

/s/ W. F. LIBBY.

PERE LORENTZ ASSOCIATES,
New York City, N. Y., April 1, 1957.

The Honorable CLINTON P. ANDERSON,
United States Senate,
Washington, D. C.

MY DEAR SENATOR ANDERSON: As you know, almost a year ago the National Academy of Sciences issued Summary Reports on the Biological Effects of Atomic Radiation, in collaboration with the National Research Council and financed by a grant of one million dollars from the Rockefeller Foundation. The reports were signed by one hundred and ten doctors and scientists, grouped into six committees. I am at present engaged in writing a book about atomic energy, for which I am under contract, and I am writing to you to inquire as to whether your committee has knowledge of any action or any research that may have been in accordance with the recommendations made by the six committees. That is, has the Congress appropriated funds for the use of any government agency in instituting studies as have been recommended, or has the Congress directed the AEC to institute studies in accordance with the major recommendations of the National Academy Committees.

1. The Committee on Genetics recommended, among other things, "that, in view of the fact that total accumulated dose is the genetically important figure, steps be taken to institute a national system of radiation exposure record-keeping, under which there would be maintained for every individual a complete history of his total record of exposure to X-rays, and to all other gamma radiation. This will impose minor burdens on all individuals of our society, but it will, as a compensation, be a real protection to them."

"That every effort be made to assign to tasks involving higher radiation exposures individuals who, for age or other reasons, are unlikely thereafter to have additional offspring. Again it is recognized that such a procedure will introduce complications and difficulties, but this committee is convinced that society should begin to modify its procedures to meet inevitable new conditions * * *"

"One important lesson which results from this study is the following: The present state of advance in atomic and nuclear physics on the one hand, and in genetics on the other hand, are seriously out of balance. We badly need to know much more about genetics—about all kinds and all levels of genetics, from the most fundamental research on various lowly forms of life to human radiation genetics. This requires serious contributions of time, of brains, and of money. Although brains and time are more important than money, the latter is also essential; and our society should take prompt steps to see to it that the support of research in genetics is substantially expanded and that it is stabilized."

Has any agency of the government undertaken research in genetics on a substantial scale, as was recommended?

2. The Committee of Pathologic Effects noted that "The increasing contamination of the atmosphere with potential carcinogens, the widespread use of many new and powerful drugs in medicine and chemical agents in industry, emphasize the need for vigilance over the entire environment."

Have there been any directed studies by your committee or any other committee of the Congress, to any United States agency to examine the "entire environment" of a community, or a city, or a rural area, or of any group of controlled individuals, whereby an analyses of the total pollution and of the total contamination might be made?

3. The Committee on Meteorological Aspects stated among other things that "the operation of any significant fraction of the earth's nuclear reactors without proper safeguards would be of concern to all" * * * The report stated further that "it should be pointed out that the release of a hazardous substance by any country may affect other countries—particularly in the same latitude belt; international control to establish and maintain high standards of safe plant operation is essential". This committee also remarked that "as additional safety factors, meteorological research to locate plants in areas where unexpected releases will do the least damage is desirable." * * *

Has your committee or any other body in Congress directed any agency of the government to take steps toward establishing any sort of international control of nuclear reactor plants? Has any scientific organization satisfactorily refuted the recommendation of the Meteorological Committee? If no, why has the AEC issued licenses for the construction of large scale reactors near New York City, Chicago, Detroit and Pittsburgh, if it is desirable "to locate plants in areas where unexpected releases will do the least damage"?

4. The Committee on Oceanography and Fisheries. This committee indicated more than any other, urgent and immediate need for world studies. In their Conclusions and Recommendations they stated, "Within the foreseeable future the problem of disposal of atomic wastes from nuclear fission power plants will greatly overshadow the present problems posed by the dispersal of radioactive materials from weapon tests. It may be convenient and perhaps necessary to dispose of some of these industrial wastes in the oceans. Sufficient knowledge is not now available to predict the efforts of such disposal on man's use of other resources of the sea."

"We are confident that the necessary knowledge can be obtained through an adequate and long-range program of research on the physics, chemistry, and geology of the sea and on the biology of marine organisms. Such a program would involve both field and laboratory experiments with radioactive material as well as the use of other techniques for oceanographic research. Although some research is already underway, the level of effort is too low. Far more important, much of the present research is too short-range in character, directed towards *ad hoc* solutions of immediate engineering problems, and as a result produces limited knowledge rather than the broad understanding upon which lasting solutions can be based."

"We recommend that in future weapons tests there should be a serious effort to obtain the maximum of purely scientific information about the ocean, the atmosphere, and marine organisms. This requires, in our opinion, the following steps: (1) In the planning stage committees of disinterested scientists should be consulted and their recommendations followed, (2) funds should be made available for scientific studies unrelated to the character of the weapons themselves, and (3) the recommended scientific program should be supported and carried out independently of the military program rather than on a 'not to interfere' basis."

"Ignorance and emotionalism characterize much of the discussion of the effects of large amounts of radioactivity on the oceans and the fisheries. Our present knowledge should be sufficient to dispel much of the over-confidence on the one hand and the fear on the other that have characterized discussion both within the Government and among the general public. In our opinion, benefits would result from a considerable relaxation of secrecy in a serious attempt to spread knowledge and understanding throughout the population."

"Sea disposal of radioactive waste materials, if carried out in a limited, experimental, controlled fashion, can provide some of the information required to evaluate the possibilities of, and limitations on, this method of disposal. Very careful regulation and evaluation of such operations will, however, be required. We, therefore, recommend that a national agency, with adequate authority, financial support, and technical staff, regulate and maintain records of such disposal, and that continuing scientific and engineering studies be made of the resulting effects in the sea."

"We recommend that a National Academy of Sciences-National Research Council committee on atomic radiation in relation to oceanography and fisheries be established on a continuing basis to collect and evaluate information and to plan and coordinate scientific research."

"Studies of the ocean and the atmosphere are more costly in time than in money and time is already late to begin certain important studies. The problems involved cannot be attacked quickly or even in many cases, directly. The pollu-

tion problems of the past and present, though serious, are not irremediable. The atomic waste problem, if allowed to get out of hand, might result in a profound, irrecoverable loss. We, therefore, plead with all urgency for immediate intensification and redirection of scientific effort on a world-wide basis towards building the structure of understanding that will be necessary in the future. This structure cannot be completed in a few years; decades of effort will be necessary and mankind will be fortunate if the required knowlerge is available at the time when the practical engineering problems have to be faced."

"The world-girdling oceans cannot be separated into isolated parts. What happens at any one point in the sea ultimately affects the waters everywhere. Moreover, the oceans are international. No man and no nation can claim the exclusive ownership of the resources of the sea. The problem of the disposal of radioactive wastes, with its potential hazard to human use of marine resources, is thus an international one. In certain countries with small land areas and large populations, marine disposal of fission products may be essential to the economic development of atomic energy. We, therefore, recommend: (1) that cognizant international agencies formulate as soon as possible conventions for the safe disposal of atomic wastes at sea, based on existing scientific knowledge; and (2) that the nations be urged to collaborate in studies of the oceans and their contained organisms, with the objective of developing comparatively safe means of oceanic disposal of the very large quantities of radioactive wastes that may be expected in the future."

"Because of the increasing radioactive contamination of the sea and the atmosphere, many of the necessary experiments will not be possible after another 10 or 20 years. The recommended international scientific effort should be developed on an urgent basis."

Has your committee or any other committee in the Congress considered the establishment of a national agency such as is recommended in paragraph 6? Has any agency of the United States Government taken steps to meet with other government bodies in an effort to "formulate as soon as possible, conventions for the safe disposal of atomic wastes at sea"? Has your committee directed any agency of the government to collaborate with other nations "in studies of the oceans and their contained organism, with the objective of developing comparatively safe means of oceanic disposal of the very large quantities of radioactive wastes that may be expected in the future"?

5. The Committee on Agriculture and Food Supplies. This committee recommended, among other things, that "The Committee therefore urgently recommends that appropriate experimentation be immediately activated to provide specific information about possible total or cumulative biological effects that might follow the ingestion of such foods. It further urges that the planning of such experiments be broadly based, and that the development of the experimental designs and details of their subsequent execution be most carefully considered in order that the emerging data will be acceptable as a basis for the crucial decisions that ultimately will have to be taken, and directly of value to the regulatory agencies charged with the protection of the public interest * * *."

"Research activities might appropriately be carried out on areas near weapons test sites where substantially greater changes in background would be anticipated. The distribution in the environment, in the soil at various depths, in the vegetation, in the wildlife, in the streams, etc., would all be pertinent. The rate of accumulation in soil as affected by land use ought to be studied. Forested land, range land, rotation grassland, and plowland, irrigated and non-irrigated, may each present a different situation. It is possible that certain of the State Agricultural Experiment Stations might be in a position to undertake limited surveys of this type on areas likely to be under their control for some considerable time in the future."

Has your committee knowledge of any experimentation being undertaken by any agency of the government "to provide specific information about possible total or cumulative biological effects that might follow the ingestion of such foods"? Also has your committee recommended funds for the Department of Agriculture, or any other government agency, to be used in undertaking the research activities in areas near weapons test sites, as recommended?

6. The Committee on Disposal and Dispersal of Radioactive Wastes—This Committee listed the following items that were considered important enough to require further study:

(1) Geophysical and geochemical aspects of ultimate disposal of highly radioactive wastes.

(2) Site selection for various nuclear facilities, particularly chemical processing plants and their location with respect to suitable waste disposal areas.

(3) Transportation of highly radioactive materials.

(4) Relationship of introduction and development of nuclear facilities to basic public health, social and economic situations extant or resulting from such development.

The Committee on Oceanography would seem to have covered this field thoroughly.

In summary, although the 1954 Atomic Energy Commission Act would seem to vest all responsibilities concerning atomic matter in the hands of the AEC, there seems to be now a public health problem which involves the land, the oceans, the air and agricultural products, and I would be deeply grateful if your committee could provide me with any record of research projects that might have been approved by the Congress, and that might be carrying out some of the recommendations of the before-mentioned committees of the National Academy of Sciences.

Very truly yours,

PARE LORENTZ.

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington 25, D. C., April 9, 1957.

Mr. JAMES T. RAMEY,
Executive Director, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. RAMEY: This is to acknowledge Dave Toll's letter of April 6, 1957, enclosing a letter from Pare Lorentz Associates, Inc., addressed to Senator Anderson dated April 1, 1957.

Be assured the letter will receive our prompt attention, and a reply will be forwarded.

Sincerely yours,

BRYAN F. LAPLANTE,
Special Assistant to the General Manager (Congressional).

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington 25, D. C., May 22, 1957.

Mr. JAMES T. RAMEY,
Executive Director, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. RAMEY: This is in further reply to Mr. David Toll's letter of April 6, 1957, requesting the Commission's comments on a letter dated April 1, 1957, Senator Anderson had received from Pare Lorentz Associates, Inc. To the extent we are knowledgeable we are happy to provide answers or comments in connection with the questions raised by Mr. Lorentz:

1. Congress has not appropriated funds specifically directed toward the establishment of a national system of radiation exposure record keeping, nor has it directed the Atomic Energy Commission or any other agency to institute such a system. Some study has been given this subject by the Commission's Division of Biology and Medicine, by the Advisory Committee for Biology and Medicine and by a number of national and international bodies including the National Committee on Radiation Protection, the International Commission on Radiation Protection, the United Nations Scientific Committee on the Effects of Atomic Radiation, and the World Health Organization. A complete system of record keeping would involve either (a) the necessity for each individual in the population to carry a card upon which would be entered the radiation exposure received at each medical examination and treatment and the radiation received from occupational exposures, or (b) the reporting of each such exposure to a central bureau by radiologists and health physicists, together with some means of accurately identifying the individual's exposure. The first of these methods, to be successful, would require the cooperation of all individuals in the population. Either method would be unwieldly. As a result of increasing interest in radiation exposures, radiologists are voluntarily making more accurate determinations of exposures actually given during examinations and treatments and are keeping better records of such exposures. A number of studies to obtain more accurate estimates of average exposures incidental to medical diagnosis and treatment in representative hospitals are under way. Records of occupational exposure are kept on individuals employed in AEC establishments. Persons

using sources of radiation licensed by the AEC are also required to keep records of personal exposure to demonstrate compliance with regulations covering such use. It may be expected that most private industries employing persons subject to radiation exposure will maintain records of exposure for purposes of legal protection.

As noted in the Commission's 21st Semi-annual Report to Congress, research in genetics was initiated by the Manhattan Project and has been supported on a greatly expanded scale by the AEC. Research in genetics is also supported independently by the National Science Foundation and by the National Institute of Health. There has been no large increase in the amount of Government-supported genetic research as a result of NAS–NRC report. While more rapid expansion could take place with a greater expenditure of Government funds, there is also a need for a large number of competent scientists interested in carrying out the studies.

2. The Congress is well aware of the problem of the increasing contamination of the atmosphere and its possible relationship to the increase in lung cancer, and has set up under the Department of Health, Education, and Welfare the Interdepartmental Committee on Community Air Pollution.

This Committee has official representation from the Department of Agriculture, the U. S. Atomic Energy Commission, the Department of Commerce, the Department of Defense, the Department of Health, Education, and Welfare, the Department of Interior, and the National Science Foundation.

The Committee holds regular meetings in order to discuss in detail the problems connected with air pollution. In addition, there is a budget supplied to DHEW through Congressional appropriation which is being used for research and survey work in connection with air pollution.

3. Some degree of international control of nuclear reactor plants is to be expected from the International Atomic Energy Agency. Such controls will apply only to reactors built and operated by members of the agency.

The Atomic Energy Commission has issued "construction permits" for power reactors at Indian Point, New York, approximately 24 miles from New York City, at Dresden, Illinois, approximately 50 miles from Chicago, and at Lagoona Beach, Michigan, approximately 30 miles from Detroit. In addition, the Commission is constructing a Pressurized Water Reactor at Shippingport, Pennsylvania, approximately 25 miles from Pittsburgh. In the case of the Pressurized Water Reactor the AEC undertook the construction of this reactor after a careful survey of the conditions at the site and the type of reactor which was to be built. It was concluded that the public would be adequately protected by the type of reactor selected and also by providing for a tight container around the reactor to contain radioactive materials in the unlikely event of a reactor accident severe enough to disrupt the heavily constructed primary reactor container system. In the case of the three privately-owned reactors, the construction permit was issued for these only after careful consideration of the general type of reactor plan and with provisos that these too would be surrounded by safety containers to protect the public in the case of an accident. As you are no doubt aware there is now in progress a hearing on the Power Reactor Development Corporation Lagoona Beach reactor.

4. A scientific committee initiated and financed by the Atomic Energy Commission, Office of Naval Research, Fish and Wildlife Service, and with the participation of the National Science Foundation has recently been established by the National Academy of Sciences. The scope of the committee is to:

1. Survey and evaluate the state of knowledge and activity in the various branches of oceanography and recommend broad programs and specific tasks that might be undertaken to advance the oceanographic sciences.
2. Facilitate joint planning among those responsible for the support and conduct of research in oceanography.
3. Stimulate coordinated studies on problems which overlap the traditional boundaries of specialized research, and identify opportunities for the application of knowledge and theory from other sciences and disciplines to problems of oceanography.
4. Develop a focal point for the compilation, exchange, and dissemination of information, and promote the efficient utilization of research personnel and facilities.
5. Provide forums for the discussion of problems of concern to all branches of oceanography (such as manpower, ship and laboratory facilities, instrumentation, data processing, etc.) and foster the search for solutions to those problems.

6. Provide for appropriate scientific representation in international meetings and furnish counsel regarding United States national interests in matters pertaining to the ocean.

It is anticipated that this committee will be a working group, as well as one to give advice which will enable the participating agencies to accomplish objectives even beyond those mentioned in Mr. Lorentz' question.

The Oceanographic Panel of the International Geophysical Year (U. S. participation financed through N. S. F.) is also actively studying phases of physical oceanography which will contribute to knowledge necessary for sea disposal of atomic wastes.

A number of research projects are supported by the Atomic Energy Commission which have a bearing on the biological effects of radioactive wastes which might be disposed of at sea. These are:

1. Woods Hole Oceanographic Institution "Biological and Radiochemical Studies of Coastal Plankton Populations"
2. Marine Biological Laboratory, Woods Hole "Studies on the Physiology of Marine Organisms Using Radiosotopes"
3. Applied Fisheries Laboratory, U. of Washington Radiobiological Surveys in the Vicinity of the Eniwetok Test Site. (This is not the exact title of any one project but is the general subject of their research.)
4. Naval Radiological Defense Laboratory, San Francisco "Study of Soil, Water, Flora and Fauna of the Marshall Islands"
5. The Fish and Wildlife Service, Beaufort, N. C. "The Accumulation of Fission Products by Marine Fish and Shellfish
6. University of Hawaii, Hawaii Marine Laboratory "Radioisotope Uptake in Marine Organisms with Special Reference to the Passage of Such Isotopes As Are Liberated from Atomic Weapons Through Food Chains Leading to Organisms Utilized as Food by Man"
7. University of Hawaii, Hawaii Marine Laboratory "Management of the Eniwetok Marine Biological Laboratory"
8. Stanford University, George Vanderbilt Foundation "Marine Biological Survey of Western Pacific"

In reference to question (6), geophysical and geochemical aspects of ultimate disposal of high-level wastes are being actively considered by a number of research groups and projects. These are described on pages 159–160 of the 21st Semi-annual Report to Congress (January 1957). In addition, a new project now in effect with Scripps Oceanographic Institute is concerned with studies of the circulation of elements of biological importance, and the dynamics of their dilution and concentration, throughout the entire geophysical environment.

5. The recommendation of the Committee on Agriculture and Food Supplies quoted here applies primarily to fallout from nuclear weapons, particularly strontium 90. The AEC has for several years been engaged in extensive research programs covering not only the biological effects that might follow the ingestion of such foods but also studies of the distribution of strontium 90 in the environment, in the soil at various depths, in the vegetation, and in animals under a variety of environmental conditions. The U. S. Department of Agriculture in certain state agricultural experiment stations has cooperated in some of these studies. The AEC has conducted studies of uptake of radioactive materials by plants and wild animals near the weapons test sites but has not found a favorable environmental condition for establishing a large scale agricultural research activity near the test site.

6. In this portion of his letter, after enumerating items considered by the Committee on Disposal and Dispersal of Radioactive Wastes as sufficiently important to require further study, we assume Mr. Lorentz intended to say that that Committee would seem to have covered this field thoroughly. These tiems have been under intensive study by the AEC but may be expected to represent basic problems in the development of nuclear energy for some years to come.

Geophysical and geochemical aspects of the disposal of highly radioactive wastes in soil have been under intensive study for more than ten years at our Hanford plant and to a somewhat lesser extent at Idaho Falls and at Oak Ridge. In these studies we have had the cooperation of the U. S. Geological Survey and the Earth Sciences Division of the National Academy of Sciences.

Studies of site selection for chemical processing plants with respect to suitable waste disposal areas are of course not made independently of the studies mentioned above.

Responsibility for the safe transportation of highly radioactive material is vested in the Department of Commerce, the Civil Aeronautics Board, and the

U. S. Coast Guard. The AEC has worked closely with these agencies and is presently engaged in studies designed to minimize hazards incidental to future transportation requirements of the nuclear energy industry.

The relationship of nuclear facilities to basic public health, social and economic situations is a broad question upon which many studies are being brought to bear; for example, the Joint Committee on Atomic Energy established in 1955 a panel of prominent persons from many professions to study the impact of the peaceful uses of atomic energy. The report of this panel was published in two volumes in January of 1956. The Joint Committee on Atomic Energy and other committees of Congress such as the Committee on Interstate and Foreign Commerce, House of Representatives; the Committee on Government Operations, House of Representatives; and the Senate Committee on Foreign Relations, to mention but a few, haxe from time to time held hearings on various aspects of this subject.

This subject has also been of interest to many other groups including the Atomic Energy Commission, the U. S. Public Health Service, the National Academy of Sciences, the World Health Organization, the United Nations, the International Labor Organization, the Rockefeller Foundation, state health organizations and many other groups. These interests are developing our knowledge of the relationship of nuclear facilities to public health more rapidly than any other aspect of public health. Social and economic impacts arise more spontaneously from economic interests.

In reference to the last paragraph of Mr. Lorentz' letter, we believe that he is in error in assuming that Congress approves individual research projects rather than approving budgets for research programs.

We trust the information supplied above will be of assistance to you in replying to Mr. Lorentz' letter. Mr. Lorentz' letter is being returned to you.

Sincerely yours,

R. W. COOK, *Deputy General Manager.*

Enclosure: Letter dated April 1, 1957.

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington 25, D. C., July 9, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: The Atomic Energy Commission approved for unclassified publication the rewritten handbook entitled "The Effects of Nuclear Weapons," copies of which are attached.

New information has been developed since "The Effects of Atomic Weapons" was last published. At the request and with the assistance of the AEC, the Armed Forces Special Weapons Project of the Department of Defense prepared the new edition. The services of Dr. Samuel Glasstone were secured as editor and the material was reviewed by the Federal Civil Defense Administration, by cognizant contractors of the AEC, and by the Department of Defense.

"The Effects of Nuclear Weapons" updates information appearing in the 1950 handbook and the February 15, 1955 release on Effects of High-Yield Weapons. It includes an expanded coverage on fallout referred to in our letter to Senator Anderson dated November 16, 1956. It bears a foreword signed by the Secretary of Defense, Charles E. Wilson, for the Department of Defense, Administrator Val Peterson for the FCDA, and the undersigned for the AEC. The handbook has been printed by the Government Printing Office which also prepared the advanced page-proof copies of those chapters dealing with fallout which were furnished to Representative Holifield of your Committee for the recent hearings on fallout.

Approval of the text by the Commission was unanimous except with respect to a number of points on which Commissioner Murray desired wording or action differing from that believed most appropriate or factual by the other members of the Commission. Commissioner Murray asked that you be informed of the points concerned; these are listed in the second attachment and comment thereon will be provided if requested.

These copies of the Effects of Nuclear Weapons handbook are being sent in advance of the release for the book which is set for publication in afternoon newspapers of Friday, July 12, 1957. When these copies were received it was

noted that the printer had omitted six lines from paragraph 10.24 on page 454. A correction sheet for that page has been included in each book.

Sincerely yours,

LEWIS L. STRAUSS, *Chairman.*

Attachments: As stated above.

Listed below are seven suggestions regarding "The Effects of Nuclear Weapons" handbook, which were made by Commissioner Thomas E. Murray but were not accepted by the Commission.

(1) That Chapters 9, 10, and 11 be submitted to the Advisory Committee on Biology & Medicine for review prior to approval for publication.

(2) That there be inserted in the Handbook a detailed Appendix of latest statistics and opinions relative to world-wide fallout.

(3) That in the last sentence of para. 9.49 which reads: "In fact the external radiation produced by the fallout from a weapon with a fission yield in the megaton range would be extremely small in comparison with the natural background radiation," the word "extremely" be deleted and, following the word "small," (of the order of —— percent)" be added.

(4) That in para. 9.94 of the Handbook, the words "can under some conditions" be replaced with the words "could be expected to" in the sentence which reads: "One is that the residual nuclear radiation can under some conditions represent a serious hazard at great distances from a nuclear explosion, well beyond the range of blast, shock, thermal radiation and the initial nuclear radiation."

(5) That in para. 10.1, the word "will" be used instead of "may" in the sentence which reads: "During the first few days or weeks after the detonation, the radiation levels may be high enough to represent a danger to exposed persons."

(6) That Chapter 10 entitled "World-Wide Fallout and Residual Radiation" give added coverage to the long-term strontium-90 hazard from local fallout.

(7) That in para. 11.122 the word "may" be deleted and the word "find" be changed to "finds" in the second sentence which reads: "The strontium may then find its way, mainly through milk products, into the human body."

APPENDIX 7

1. INFORMATION FURNISHED TO THE JOINT COMMITTEE BY STANLEY H. CLARK, BALTIMORE, MD.

2. INFORMATION FURNISHED TO THE JOINT COMMITTEE BY ALDEN A. POTTER, BETHESDA, MD.

8420 LOOKOUT MOUNTAIN AVENUE,
LOS ANGELES 46, CALIF.,
February 22, 1957.

Mr. GRAHAM DUSHANE,
Editor, Science,
1515 Massachusetts Avenue NW.,
Washington 5, D. C.

DEAR SIR: The article on Sr–90 content in human beings by J. L. Kulp, et al. (*Science*, February 8, 1957) may possibly be interpreted by some readers as indicating that there is little danger at this time from Sr–90. Actually that is very far from the truth.

First, consider the International Commission of Radiological Protection's recent (November 1956) reduction of the maximum permissible dose. It is now considered to be one-third (⅓) of the former value or five roentgens per year (this is occupational). Next we must always consider the occupational maximum permissible concentration separately from the maximum permissible concentration for the entire populace. The accepted reduction factor is ten—that is, the populace maximum permissible concentration should not exceed 0.5 roentgens per year (5×0.1). Applying to the Sr–90 maximum permissible concentration, we see that the populace m. p. c. is 33.3 micromicrocuries gram of calcium rather than the 1,000 micromicrocuries/gram of calcium as stated in the above-mentioned article. In the light of this value let us look at the actual Sr–90 content in human beings from different locations on the earth.

We see that the *average value* which is present in human beings today is only 1/330 of this m. p. c. and will become 1/33 (to 1/16) of the populace m. p. c. by

1970 even if no further nuclear devices are exploded! Now let us look more carefully at the concentration of Sr–90 in some of the 600 specimens analyzed. We find that 13 out of these 600 specimens actually exceed 1 micromicrocurie per gram of calcium *now* (through 1955). Or that they will have 10 to 20 micromicrocuries per gram of calcium by 1970 even though no further tests are conducted! These 13 specimens represent about 2 percent of the specimens which, if applied to the world population, is about 50,000,000 people! It will be noted from Fig. 2 of the *Science* article that these are mostly young people, 20 years or younger.

Of course, if tests are conducted at the same rate as in the past ten years, these 50,000,000 people on the surface of the earth would almost certainly be carrying an amount of Sr–90 equal to or even greater than the populace maximum permissible concentration of 33.3 micromicrocuries/gram of calcium!

Finally, we should note on page 68 of the British Research Council's Report "The Hazards To Man Of Nuclear And Allied Radiations" the following paragraph "In the light of knowledge at present available, we should feel that immediate considerations were required if the concentration (of Sr–90) in human bones showed signs of rising greatly beyond *one-hundredth* of that corresponding to the maximum permissible occupational level."

I believe that this information merits the attention of scientists and public alike.

Sincerely,

STANLEY H. CLARK,
Medical Physicist, Cedars of Lebanon Hospital, Los Angeles, Calif.
NUCLEAR DIVISION, GLENN L. MARTIN CO., BALTIMORE 3, MD., *March 15, 1957.*

June 10, 1957.

Re hearings on the problem of radioactive fallout from nuclear weapons explosions.

Representative CHET HOLIFIELD,
Chairman, Subcommittee of the Joint Committee on Atomic Energy,
Room F–88, Capital Building, Washington, D. C.

DEAR MR. HOLIFIELD: I would like to submit for inclusion in the Congressional Record my feeling, as a scientist-citizen, on the subject of fallout and radiation injury. I would also like to make a suggestion for resolving the current conflict regarding testing of nuclear devices.

* * * * * * *

Although the medical genetic radiation exposures do exceed the fallout genetic radiation exposures in the United States, these medical exposures are knowingly received under medical supervision. This is not the case with world populace when we consider exposure from radioactive fallout. This, I feel, is the main point—we cannot expect all people to accept biological damage no matter how small or well justified we feel as a nation in exposing ourselves. *If there was general agreement* in the scientific community that there was negligible damage then such exposure would probably be acceptable.

Since the government has clearly stated that the testing of nuclear devices must be continued if our national security is not to be jeopardized, then we should look for solution to this problem which will not appreciably hinder future testing programs. The currently considered solution, that of reducing world nuclear testing to a few megatons per year, obviously does not fulfill the national security need. We must provide a means for testing nuclear devices by other nations as well as ours since world wide development of nuclear devices seems inevitable.

Probably the only solution to this problem is to make tests outside of the earth's atmosphere, i. e., in space. Today, 1957, this is technically feasible. We are now in a position to launch such nuclear devices on missiles that go well above the atmospheric envelope. I will not belittle the test difficulties; the difficulties in obtaining detailed test information; however, I feel certain the problems in this area can be resolved. Certainly the magnitude of an explosion and most of its physical characteristics can be ascertained during detonation in space.

The point I would like to stress technically is that it is completely safe from the radiological hazard standpoint to test weapons in space. (Probably the most serious hazard would be the great light intensity produced during such

tests.) What happens to the radioactive fission products when a nuclear device is exploded, for example, at 100 kilometers? Particles of 2 microns diameter (1 micron equal 1/10,000 centimeter) take a little over three years to fall to the earth's surface from this altitude. Particles of greater diameter take much less time to come to earth (at 8 microns diameter a particle takes about 130 days to reach the earth's surface). However, when the particle diameter approaches 0.2 micron or less, a new phenomena begins to occur. The light from the sun actually will push the particles out of the earth's gravitational field and, in fact, out of our solar system. Thus, for nuclear explosions in space with all particle sizes probably occurring of less than 1 micron, we have a means of cleaning up the fission products; in fact, sweeping them out into space. Surely this is the ultimate in a radiologically safe testing program. It is my hope that this means of resolving the nuclear testing debate will be investigated. If greater costs are necessary for such tests I feel certain that they will be jusified in the light of human well being.

STANLEY H. CLARK.

MEDICAL X-RAY EXPOSURES—NATIONAL VARIATIONS, INTEGRAL DOSES, ETC.

Stanley H. Clark,[1] National Biophysics Conference, Columbus, Ohio, March 4–6, 1957

INTRODUCTION

The development of the uses of atomic energy has focused greater and greater attention on the biological effects, particularly, the effects on man, of all ionizing radiation. The relative furor over the biological effects on man of radioactive fall-out has led to the refocusing of attention on existing and accepted uses of ionizing radiation. Thus, the pressures exerted due to new problems associated with uses of nuclear materials has caused a re-evaluation by a U. N. Committee, by Government bodies, scientific organizations, and individuals, of man's total radiation environment. Most, or all of these studies have indicated that of all the "men created" radiation exposures, that the uses in medicine are currently the most significant. Thus, we find that in the United States National Academy of Science Report, "The Biological Effects of Atomic Radiation" and in the British Medical Research Council Report "The Hazards to Man of Nuclear and Allied Radiations," as well as the U. N. Report on the biological effects of radiation that the medical uses of radiation have been subject to rather critical analysis.

Here is a comparison of the genetic exposure values in the medical uses of radiation as stated in the various national reports.

Values are for the first 30 years of life, and assume exposure at the same rate as at present and in the immediate past.

1. The United States as given in the National Academy of Sciences Report—3 roentgen.
2. The British, as given in the Medical Research Council Report—0.6 roentgen.
3. Sweden—Sivert's Study—0.78 roentgen.
4. Australia—Martin's Study—0.304 roentgen.
5. The U. N. Radiation Studies Committee Report—not yet completed wide range of values for different countries.

Let us now see what factors could account for these differences. (There is no particular order in this listing of factors.)

(*a*) Differences in actual number of diagnostic exposures to the populations of the various nations is one of the most important factors. Since each report sums medical exposures and then divides this lumped sum (in roentgens) by the numbers of people it makes considerable difference how many people in a populace have how many exposures. Related to the number of exposures per populace is no doubt standard of living of that particular nation.

(*b*) We might also ask, what medical uses are included in each nation's report. This calls attention to the fact that only the United States value includes therapeutic uses of X-rays (for non-malignant conditions), and uses of radioisotopes in medicine. These uses account for about 15% of the 3 roentgen value in the National Academy figure.

[1] Cedars of Lebanon Hospital, L. A., Consultant, Medical Division, Oak Ridge Institute of Nuclear Studies, Physicist in Radiology, Medical School, University of Southern California, now with the Glenn L. Martin Company, Nuclear Division, Baltimore 3, Maryland.

(*c*) Difference in physical factors and techniques represents a significant variable. There is considerable more control of physical factors in England and in Sweden due to a combination of factors—socialized medicine; physicists have a closer relationship with radiologists; and early recognition of radiologic physics as a profession. In the United States one finds the private physician performing fluroscopy as well as other medical specialists, dentists, chiropractors, general practitioners, etc., using X-rays with few exceptions without any consultation with a radiologic physicist.

(*d*) Another factor that should be remembered is that of the origin of the various data which were used for averaging.

1. The National Academy averaged from a few United States hospitals and medical groups, however, correlating this data with nationwide uses of X-ray film, etc.
2. The British used hospitals in England and Wales which have hospital physics, groups and extrapolated for the rest of England. "Gonadal doses are based primarily on 1500 patients at one large hospital, (where incidentally particular care is taken to reduce the gonad dose to the minimum)."
3. In Sweden, most of the medical uses of radiation were considered in obtaining the average genetic exposure, no doubt the study was strongly influenced by the Institute of Radiopsysique in Stockholm where procedures are under direct supervision of a physics group.
4. In Martin's report on gonadal exposure due to diagnostic uses of X-rays he uses almost all available literature and the ratios of various diagnostic procedures in one hospital are the basis for his dosage estimates.

(*e*) Additional explanatory notes on factors which contribute to the range of exposure values.

1. The British Medical Research Council figure is really not comparable with the United States value since—to quote from that report—"The value of 22% (0.6 roentgen) should be regarded as a probable lower limit rather than as an estimate. A realistic estimate of the radiation contribution from diagnostic radiology might be considerably greater than this figure". They also discuss the possible factors of 2, 3, and even 10 times this lower limit.
2. In the Australian exposure analysis, J. H. Martin states "that the turn over of patients in the X-ray diagnostic department had already doubled" at the time of his presentation (November 1954), thus his values when brought up to date would be similar to, or greater than, the values for Great Britain and Sweden.
3. S. B. Osborn, whose work forms part of the basis for the British Medical Research Council's estimate discusses in his analysis in Lancet that examinations of the hip and lumbar spine, pyelograms and pelvimetry, although they constitute only 7% of the total number of examinations, none-the-less contribute 75% of the total genetic dosage. Obviously, even minor variations in these procedures from one hospital to another, would cause significant differences in the genetic exposure values. It is interesting to note that Osborne finds that 26.3% of the total populace genetic exposure takes place during radiographic exposure of the fetus in pregnant women.

What incident values mean in terms of whole body effect—the induction of cancer and the shortening of life span.

(*a*) There is need for the integral dose concept when evaluating the medical uses of X-rays. Discussion of radiation exposure of the gonads in man and the ovaries in women require measurements in the vicinity of the reproductive organs and some correction in women for the depth of the ovaries, however in this case we are concerned with the dose at essentially a point and need not be concerned with the energy absorbed in the entire body. However when considering the hazard from diagnostic uses of X-rays which may produce damage in terms of more general tissue damage we need a different concept. The concept most appropriate for evaluating such general body injury is that of the integral dose, or absorbed dose. Specifically, the two important effects related to integral dose are increased incidence of leukemia and shortening of life span. Both are known to be associated with exposure to ionizing radiation.

It is generally agreed that shortening of life span is strongly correlated with the amount of radiation energy abosrbed in the body. This effect then can be most appropriately discussed in terms of the integral dose—a concept originating in England, I believe—it is simply the product of the number of grams or cubic centimeters irradiated, and the number of roentgens to each of the cubic centimeter volumes. Such values are calculated from either X-ray distribution patterns known as isodose patterns, or from an equation developed by Johns. (6)

In general, the first technique is the more accurate. However, for the sake of our calculations, the John's equation has been used to obtain integral doses. When isodose curves were used the area between each isodose line was measured, using a planimeter. This area was then multiplied by the field height and the average roentgen dose to that volume to give the integral dose for that segment. These segment values were then summed to give the total integral dose.

Before comparing particular values of diagnostic integral dose, let us consider how the integral dose changes with change in the energy of the incident X-ray. Assuming that field size and exit dose-rate is kept constant how does the integral dose vary?

The integral dose decreases rapidly with increased X-ray kilovoltage assuming a constant exit dose.

Now turning to the diagnostic usages, we note that the patient exit dose must be essentially constant, regardless of KV, in order to produce useful film darkening or fluoscopic light intensity. This fact when considered in conjunction with the area under the depth dose curve (which is proportional to the integral dose) shows very clearly that in the range from 40 KV to 1 mev that the integral dose decreases substantially with increase KV—thus, we might ask why the diagnostic radiologist does not continue to raise the X-ray KV and thereby reduce the integral dose. There are at least two physical reasons why this is not wholly feasible:

1. The absorption coefficients for different elements in the body, i. e. bone and tissue become so similar at higher kilovoltage that very little contrast is obtained at energies above a few hundred kilovolts.

2. The response of film (and fluorescent screens) decreases with increase KV for a given incident intensity. It becomes evident that there are optional KV values for various parts of the body, depending strongly on what information one is most interested in and the thickness of the particular body cross section. It should be remarked that if too much filtration is used at high energies there will be no reduction of integral dose. There will be a decreased incident dose, but the exit dose must be increased because of the decreased film response at higher KV.

(*b*) Since the increased incidence of cancer, primarily leukemia, is related to the actual bone dosage as well as to the integral dose, it is important to note the depth dose distribution as well in evaluating this particular hazard. It has been pointed out by Hardin Jones and others, that the dosage to long bones, i. e., the dosage to the rib cage, in chest X-rays would be particularly important insofar as the production of leukemia is concerned. It would be well to mention at this point the studies that indicate leukemia is produced by even small amounts of radiation. The best evidence is from the following studies:

1. Studies by Alice Stewart, J. Webb (7, 8), etal in England which indicate an increase in incidence of several malignant diseases including leukemia due to diagnostic X-ray exposures of the pregnant mother, particularly abdomenal exposures. Secondly studies of the survivors of the Hiroshima and Nagasaki nuclear explosives (9, 10), and thirdly exposure of radiologists (11) in the course of their professional activities.

2. Studies which indicate that somewhat larger radiation doses will produce leukemia include a series of infants treated with X-rays for thymus condition (12) and secondly X-ray therapy of anklosing spondylitis (13).

The statistical analysis of this information, as well as the linear relationship between incidence of leukemia and integrated dose is given strong support by Hardin Jones of University of California, in material which will be published in the near future. Shortening of life span as caused by radiation has been borne out by many animal experiments by the shortening of life span of radiologists, and by patients who have been treated with X-rays. Here again, the dose is linear with respect to shortening of life span. According to Jones about 10 days should be subtracted for each roentgen received of whole body radiation. The integral dose ranges from about 11,300 to 56,000 gram-roentgens for 1 roentgen incident dose. This assumes a range of X-ray energies corresponding to 2 mm of aluminum half value layer to 2 mm of copper half value layer.

In the course of using X-rays for treatment of malignant diseases, we encounter total integral dosages ranging from 1 million gram-roentgens to many million (30 or 40) gram-roentgens. This wide range is due primarily to the variation of field sizes that are used for lesions of different dimensions, and to some extent of KV. These large integral doses are actually admin-

istered in daily doses—as many as 30 or 40—in the course of a single treatment. To cite a specific example—using a 5 cm circular field at a focal skin distance of 80 cm with a half value layer of 4.00 mm of copper. The daily dose of 100 roentgen produces an integral dose of about 19,800 gram-roentgens, (remember that one roentgen incident dose produces about 11,300 gram-roentgens). Now let us compare this therapeutic value with some common diagnostic procedures. A film of the lumbar spine taken through the AP direction with the following physical factors—AP thickness 20 cm F. S. D.–71 cm, KV–70, MAS 160. Focal film distance 91.44 cm (36 in.) produces an incident dose per exposure of 4.3 roentgen. This produces an integral dose of 28,810 gram-roentgens. If we take a lateral film of the same person, we will obtain an integral dose of about 150,000 gram-roentgen or the equivalent of some 7½ times the daily integral dose cited for the above cancer therapy! Or to make another comparison, about 3 times the present maximum permissible exposure for one year period! This value would be greatly increased for a heavier person. The explanation for the larger integral dose as compared to the therapeutic dose is almost entirely due to the increase in field size. In the therapeutic example, the field size used was about 20 cm^2 in the diagnostic case it was 1487.5 cm^2 (a standard 14x17 inch film). Of course, the actual X-ray field size as determined by the cone used was circular and somewhat larger even than the area used. The integral dose in chest photofluoraphy would be about 10,000 gram-roentgens.

In fluoroscopy, the literature cites incident dosage rates from 5 to 20 roentgens per minute, depending undoubtedly on the amount of filteration and body thickness. This dosage rate would produce integral dose values from about 30,000 gram-roentgen per minute to about 120,000 gram-roentgen per minute. Frequently fluoroscopies last as much as 5 or 10 minutes which means the absorbed energy approaches that which is actually used for some small field cancer therapy. What does this mean in terms of shortening of life span and increased incidence of cancer? In the case of the shortening of life span we found that a 1 roentgen incident dose (which amounts to about 11,000 gram roentgen would decrease life span statistically by about 10 days. Thus, a single fluoroscopic examination would shorten the life span by as much as 500 days (at a 20 r per minute dosage rate). Or the lateral pelvic radiograph would shorten the average life span by about 140 days! But let us see how these figures compare with some other factors that are known to shorten life span (unpublished, Hardin Jones-University of California).

	Years
25 percent overweight group	3.6
Heart murmur	11
Rapid pulse	3.5
Varicose veins	0.2
Trace of albumin in urine	5.0
Epilepsy	20.0
Skull fracture	2.9

It should be noted that when applied to the total populace millions of man-years of life are lost due to medical radiation exposure (about 7,000,000 man-years each 30 years at the current exposure rate).

With respect to increasing the incidence of cancer particularly myeloid leukemia I would simply like to make a general statement regarding the increased incidence with respect to chest photofluography as a significant example. We find that 1r exposure per year gives a probability of 1 in 100,000 to 1: 1,000,000 of developing leukemia per average individual (7) (14) (15). This probability applied to the 15,000,000 people in the United States who have chest X-rays (in mass chest X-ray surveys) annually would amount to an increased number of cases of myelogenous leukemia; due to these chest X-ray exposures alone 15 to 150 cases per year and each year thereafter. There is in addition speculations that some individuals are genetically more asensitive to the induction of radiation leukemia. Thus a particular sub-population might have a considerably higher probability of the occurrence of radiation induced leukemia.

MISCELLANEOUS-CONCLUSION

Finally let us consider the exposure to X-ray technicians in the course of their training, there are some 40,000 in the United States. They divide up into pairs

and go through the entire radiographic series of exposures normally encountered in diagnostic X-ray work. The genetic exposure for 35 procedures amounts to about 5.6 roentgens for the male technicians and 6.3 roentgens for the female technicians. This exposure corresponds to perhaps 20 to 30 roentgens incident dose (not greater) or about 10 to 15 roentgens of whole body radiation (in terms of integral dose). Thus in this group of technicians due to their X-ray exposure during training we might expect (using a probability of 10^{-6} per roentgen per year) some four cases of radiation induced leukemia per year. The additional exposure in the course of their work is not considered. Even so, since X-ray technicians are generally young people (at the time of training) we would expect this increased incidence of radiation induced leukemia to amount to about 160 additional cases (normally one would expect about 240 cases of both lymphatic and myelogenous leukemia). Hardin Jones states that the leukemia doubling rate is about 30 roentgens full body exposure. Which would give a figure of about 120 cases of radiation induced leukemia. It is hoped that this estimate could be confirmed from actual death statistics of X-ray technicians.

BETHESDA 14, MD., *July 5, 1957.*

HON. W. STERLING COLE,
Joint Committee on Atomic Energy,
Washington, D. C.

MY DEAR CONGRESSMAN COLE: Through your kind services I beg to submit the enclosed "Critique of Scientific Knowledge" for entry, as the Committee may see fit, in the record of the hearings on The Nature of Radioactive Fallout and Its Effects on Man, held in May-June.

The Kremlin seems to have shifted its position, softened its opposition to "western" genetics which they have ardently rejected—until it came handy in their cold war in Japan against *our* bomb tests.

At the suggestion of the Committee Technical Advisor I am asking the following geneticists with whom I am acquainted to comment, to the committee on copies sent them.

Dr. James F. Crow, National Institute of Genetics, Mishima, Japan.
Dr. Carl C. Lindegren, Southern Illinois University, Carbondale, Ill.
Dr. Stanley H. Emerson, Atomic Energy Commission, Washington, D. C.

Very truly yours,

ALDEN POTTER.

A CRITIQUE OF SCIENTIFIC KNOWLEDGE

Keep that which is committed to thy trust, avoiding profane and vain babblings, and oppositions of science falsely so called (I Timothy 6.20).

The evidence adduced in these hearings on the effect of radioactive fallout on human and other life has shown that even a considerable enlargement of test explosions will not increase the incidence of radioactivity materially beyond what all forms of life have experienced from time immemorial.

A prime consideration is the growing belief that most of the radioactivity that is injurious can be eliminated from military weapons by tests now being planned and conducted, so that possible danger to future generations in case of war will be correspondingly reduced. The larger, fusion bombs are less radioactive in proportion to the success that may be attained in eliminating fission, as in "triggering" the explosion. This may explain the Kremlin's current readiness to suspend tests so they can catch up with our "classified" progress toward clean bombs, while shedding crocodile tears over the genetic horror which they have subtly helped "western" geneticists implant at the Japanese National Institute of Genetics at Mishima.

The attempt to make medical science "objective" has turned on statistical theory and practice which is leading to a great deal of confusion as to the applicability of degrees of probability thus determined. This source of misinformation is by no means confined to research in radioactive fallout as presented in these hearings, but extends over the whole field of science. It will therefore be necessary to attempt some clarification of these basic disputes as they affect the argument over whether observed effects may be linearly extrapolated (whether the extent of biological injury by radioactivity is directly proportional to the extent of such activity, however small), as against the existence of a "threshold" or range of radiation that is either beneficial or at worst not injurious to any life. This critique will contend that thresholds are the rule, not the exception, in nature. Moreover, insofar as a threshold is biologically determined, we shall argue that it cannot be a fixed factor in the survival of any species because of adaptive changes in the organisms involved.

Senator Anderson has cited such an adaptation in the case of the resistance of insects (flies) to DDT; and there are many other such cases in recent experience with insecticides. This factor of adaptive change has been so widespread in medical research that in 1954 the University of Pennsylvania's medical school cooperated with Naval Research in organizing a symposium on drug resistance at the Statler Hotel in Washington; and thereby hangs a tale. The honor guest and speaker at dinner was Dr. Cecil P. Martin of McGill University in Montreal, Canada. He was called upon to speak because of an essay, "A Non-Geneticist Looks at Evolution," published in the American Scientist shortly before, in which he assailed "Western" genetics on the ground that it has produced an untenable theory of evolution, that is, the mutation-selection theory.

This view has gathered some support even among geneticists; witness the recent note (Science, May 10, 1957) of Lindegren and Braun criticizing the views of Dr. George Beadle of the California Institute of Technology as given in his presidential address to the American Association for the Advancement of Science, for his too confident proposal to call nucleic acid a "living" molecule because it is a "carrier" of genes in heredity. The essence of this question lies in the way the species pattern is carried. Is it by a template—a minute replica as Dr. Glass contends—or is the system like our cultural information system, linguistic and therefore *meta*physically informational like an engineer's handbook?

It should be unnecessary to record the views of Dr. Martin here for they have been available in a treatise published last year by the eminent medical publishing house of C. C. Thomas of Springfield, Illinois, entitled "Psychology, Evolution, and Sex." But the evidence adduced in these hearings by the panel of geneticists from the National Academy of Science has studiously omitted any reference whatever to these conflicting opinions, quite as they have been omitted from any and all proceedings and reports of the Academy and, as to the Martin treatise, also from the pages of Science where the book has not been reviewed after almost a year since its publication.

It will be necessary, therefore, to try to clarify the relation between the Darwinian views of Dr. Martin and some few geneticists whom our Academy has deliberately ignored, and those set forth by the Soviet scientists at a recent conference in Japan on genetics where they spoke in the terms of Mendelian theory for the first time since the days of Trofim Lysenko. Is it indeed a mere coincidence that the mechanistic materialism of our Academy with its pretense of

"objectivity" now serves in furthering the curtailment of bomb testing just as the Russian cold war is so intensifying its peace offensive as to produce riots before the American embassy in Tokyo? Are we not ourselves so supersaturated with the prevalent anti-Darwinian philosophy that we refuse to examine such a scholarly treatise as that of Cecil Martin which counters the false alternatives of an alleged conflict between military and genetic security? Only the mutation-selection doctrine with its elmination of competitive stratagems in organic evolution can serve the communistic pacifism of Soviet propaganda; and it is with a sudden acceptance of this idea that they carry the war into Tokyo!

A clarification of these issues on an honestly open-minded, objective basis entails a thorough reconsideration of the basic tenets of *scientific empiricism* which define "the scientific method" ("Scientism" and "positivism" are other terms for this "unity of science" philosophy) as purely inductive. Such a reconsideration is supported by the rising tide of literature indicating the imminence of a conceptual revolution in science. This deductive revolt is renewing the conflict between science and the anthropocentric bigotry which gave rise to the Scopes trial in Tennessee instigated by William Jennings Bryan. This court case sought to ban the teaching of a theory of evolution that does not admit the uniqueness of man which is today propounded by the chemical theory of genetics and the origin of life because, very obviously, *human affairs are certainly not chemically explicable.* Man does not live by bread alone; *but neither does any other form of life.*

The bigotry of this anthropomorphic theology has unmistakably injected the pontifical edict that an "emergent" evolutionary theory may be anthropomorphic upward *to* divinity, but not upward *from* monkeys, in its "extrapolations." Our Fundamentalists thus create a self-idolatry—a God in the image of man; an authoritarian threshold that may not be crossed even by the authorities. This prideful conceit that man is peculiarly unique not only has no support in the Christian Gospels but it seems to beget a peculiar predilection for statistical extrapolation, while banning biological analogy, as scientific evidence.

Mice are not men; so science must perforce extrapolate averages (statistical data) as a "first approximation" or "educated guess," the while indulging in crash projects, not to test empiricism against an alternative postulate, but to "prove" that extrapolations (predictions) are correct and so justify, by pragmatic "proof", the public policy already adopted in "playing safe" with probabilities. This is called "verifying the hypothesis" with "observational evidence." Its successes are proclaimed from the housetops; its failures suppressed like a Nobel Prize gone sour.

In assailing this materialistic biology it would be well to cite further evidence, from outside these hearings, that it does exist and is, indeed, censoriously entrenched in scientific literature and training for "academic freedom" in research. The popularity among biological empirics of a small book written by Prof. Erwin Schrödinger, author of the principal equation of the so-called "quantum mechanics" of atomic physics, "What Is Life?", with its attempt to forecast a physical answer, is attested not only by numerous reprints (including a paperbound, popular edition) but also by the widespread opinion, urged most recently by Linus Pauling in a lecture at the National Institutes of Health in Bethesda, that the genesis and genetics of life can and ultimately must be defined in purely chemical terms. Any other outcome would, *ex cathedra,* be a betrayal of progress in "science."

Since these hearings were recessed early in June, an article has appeared in Science (June 7) based on another lecture at CIT (alphabetics for California Institute of Technology) by an Iowa biophysicist (Robert Sinsheimer) on "First Steps Toward a Genetic Chemistry." Here "steps" in progress *toward* the end *sought*—toward what "we *shall* discover" chemically—are recounted as if time were reversed by some extrasensory perception. The facts are "not a sufficient proof * * * but in a way it is *satisfactory* to believe that the physical basis of the gene—the factor that is passed on from cell generation to cell generation—is physically conserved * * *." (Just as it was satisfactory to believe that "parity" was "conserved" in quantum mechanics—until it was shown, not first by observation, but by straight thinking, that it was untenable however satisfying!)

To our biophysicist certain chemical correlations have provided "a *pleasing* confirmation of our hypothesis," even though inconsistent with other facts. To get rid of these embarrassing obstacles to *pleasure* "more refined techniques could prove to be of *great value*" in the "*hope* that the development of a genetic

chemistry will *help* * * *." Why, indeed, are "elegant tracer studies" credited with a "*pleasing* result"? Why do "we know *painfully* little"?

Obviously because "we" are extrapolating our pullets—counting them before they are hatched. Come what may, "we" are not going to hatch any cockerels as long as any refining of techniques (or elaboration of hypotheses) remains to renew the hope that springs eternal in the chemical breast that we shall soon know how to sex them, not by the Japanese manual methods after hatching, but chemically, before the eggs are laid. Some day there will be an RNA for sex, chemically the same for all life from virus to vireo to mastadon.

Here, indeed, is an endless frontier for scientists; a fiscal rathole down which appropriations and empirical data can be poured endlessely before reaching any conclusions; such as foreign-aid policy for Japan to provide a chemically immaculate conception to displace the recently legalized abortions that are keeping Japan (and China, too) from being any further "under-developed"; that is, overpopulated. Why, indeed, worry about poverty if all we need do in the matter of a trait called parental care is to take the long last step in genetic chemistry, to wit, find the proper, parental test-tube in the gene-bank kept under lead to exclude radioactive fallout? We are definitely assured that there *is* a chemistry of the gene (not yet correlated with DNA chemistry, but soon to be) which, *when* "we have become sufficiently advanced in our understanding" of the raveled sleave of mitosis, *will* enable us to "demonstrate the action of a gene *in vitro*"—so we can live *in vitro* for nine months and then have plenty of fresh milk.

To force a reconsideration of the empirical "unity of science" is more of a task than can be encompassed by this brief critique. Such a reconsideration might, however, be invited by a rather categorical review of the high spots in this concaptual revolution as dimly perceived despite the din of data in the process of erecting our scientific Tower of Babel. Conceivably we might thus stir the well-known, open-minded curiosity of scientists in their zealous search for ways to "ring out the old; ring in the new; ring out the false, ring in the true." For not one but many minds are needed in the process of dismissing all the facets of fallacy involved in a postivistic "idealism" which obscures reality by making it synonymous with actuality so that "objective" means a consensus of *subjective* judgments as "verified by experience," pragmatically.

Life on Earth, as a whole, has no opportunity for the unlimited expansion in which it seeks to indulge. For this reason what men, and all other organisms, have most to fear is not the physical environment and its accidents, but far more what other biological occupants ("fellow creatures") do to that environment in the struggle to survive. What any and all biological coalitions do is not purely physical or fortuitous. It is expediently adaptive in its strategic choices so that all free-will, animal life requires eternal vigilance to choose aright and avoid extinction at the hands of other predators who are also exploiting other organisms as "renewable resources," sometimes symbiotically.

Among men, in a civilized context, Disraeli put the case for vigilance against misinformation in a retort to "factual" argument by the Loyal Opposition in parliamentary debate: "There are three kinds of lies; white lies, damned lies, and statistics." Since then there have been frequent protests against empirical "objectivity" among "experts" who employ "factual" correlations to verify hypotheses. These have pursued the pattern, reflecting Christ's warnings against false prophets set forth by St. Paul to Timothy telling him to avoid "profane and vain babblings, and oppositions of science falsely so called."

There have been side-splitting satires, like Chick Sales' "The Specialist," and, less biting but more specific, Anthony Standen's "Science Is a Sacred Cow" featured by the author's review, with lampooning cartoons, in LIFE seven years ago. Lately a physical chemist turned social philosopher, Prof. Michael Polanyi of Manchester, England, has severely indicated *scientific empiricism* in America in a paper read before a symposium on "Fundamental Concepts and Units of Science," published in Science this past winter.

Most recent and satirical of all is a contribution from Cornell University by zoology professor LaMont Cole, "Biological Clock in the Unicorn" (Science, May 3, 1957). This paper so aptly caricatures statistical correlation in verifying an hypothesis that it is astonishing to find, following it by only two weeks in the pages of Science, the same "quantitative information about the effect of radiation on human health" as that presented before this committee by CIT's Prof. Edward Lewis on "Leukemia and Ionizing Radiation" which Dr. Shields Warren rejected as inadequate evidence of causation in leukemia, supported editorially as follows (DuShane, Science May 17, 1957, p. 963, "Loaded Dice"):

"E. B. Lewis shows that there is a direct linear relation between the dose of radiation and the occurrence of leukemia * * * The meaning of such findings is that any amount of radiation takes its toll of the population and any increase takes a greater toll * * * We are approaching the point at which it will be possible to make the phrase 'calculated risk' for radiation mean something a good deal more precise than the 'best guess.' It is apparent that the atomic dice are loaded. The percentages are against us and we ought not play (with bomb tests) unless we must to assure other victories."

The movement toward clean bombs for the West which was revealed in these hearings and later publicized by the President (and caustically condemned by the Kremlin!) has taken the wind out of the Schweitzer sails (and the Pauling Petition) as related to leukemia and strontium 90 so that what remains of the loading of atomic dice by statistical correlation is now confined to genetic effects as alleged by the panel from the National Academy of Science before the Committee on June 4.

If it is not true that (DuShane) "much can be learned about biological reactions (in man) by appropriate statistical and epidemiological studies," such as that of leukemia conducted by a geneticist and statistician (Lewis) who has the "quantitative information" but not the facts about the disease (the recent rise in the statistical incidence of leukemia has been due, not to improved methods of diagnosis, much less to any increase in casual factors, but to the use of penicillin and other "wonder drugs" to save the patients from infections to which bad blood makes them very susceptible), it is equally fallacious to conclude that a correlation between chromosomes and the statistical results of sexual crossing reveals the true character of survival values in organic evolution.

By the same token it is not competent to conclude from a "linear relation," as did Professor Crow before the Committee, that "death, disease, and misery" produce "natural selection" without considering the occasion for such phenomena; for example, war, famine, and pestilence among men, which would be extremely difficult to correlate with any genes without even greater stretching of hypotheses than has as yet been employed in genetics. ("To multiply auxiliary hypotheses is to goropise." See "The Principle of Simplicity" by Lewis Feuer, Philosophy of Science, April, 1957.)

It is not because fruit flies are not men that the monstrous effects of laboratory irradiation do not prove the thesis that the human race will suffer from bomb tests for centuries to come. It is because mutations are not adaptations that this conclusion is unwarranted, either for men or for fruit flies. Gene injuries are as possible as any other anatomical damage from irradiation. But that they persist as recessives throughout a population (without benefit of the dysgenic effects of medical science among men), is not proved by selected statistical averages that destroy the facts.

Mutations, when they do occur, are baneful, indeed; for they destroy the hereditary homeostasis of the species in much the same sense that a burning of books can destroy a cultural heritage. They are *devil*-utionary, not evolutionary. Unlike adaptations to meet competitive pressures they do not remodel the species for survival and become, as Martin contends, "lingering modifications" which do evolve new genes in the course of unobservable time—time which is measured, not in terms of sidereal or sexual events (years or generations) but in terms of marginal elements in interacting stratagems that cannot possibly be reduced to "quantitative information."

Adaptive changes do not occur in detectable form for easy correlation; but they are not therefore mere accidentally adapted mutations. They are teleological expedients, intentionally produced, in the unobservable realm of the microcosm. This is, indeed, an unverifiable hypothesis. But it is not a "goropised" set of hypotheses devised to verify each other in an endless tautology; nor is it untrue because it is unamenable to empirical confirmation by "the scientific method," as was the case with a similar hypothesis in quantum mechanics, to wit, the conservation of parity, which was found to be *predictably* and *testably* false because it pertained to purely physical, inorganic structure. Not observation, but theory, made this discovery!

In biology theory must perforce pursue analogy—the judging of all living processes by our own, in aspects which every man-on-the-street knows and which require no expertise explanations; and these processes are not predictable in their course. They are expedient; just for today. While they cannot violate the natural laws of the physical order, they are not governed by them. They

are "cybernetically" governed, by negative feedbacks that involve a correction in the current theory of information—a corrective which postulates the existence of a metaphysical factor, that is, a dialectical system of commication analogous to human communication in everyday affairs wherein *conditioned* reflexes are a matter of the most familiar processes of modern education. As Whitehead has pointed out, the more civilized we are, the more automatized is our behavior. (Cf. Hayek, "The Use of Knowledge in Society," Am. Econ. Review, September, 1945.)

Concurring with the Martin thesis, Lindegren and Braun (Science, May 10, 1957) cite literature which holds that gene mutation *per se* does not afford a satisfactory explanation of evolution; also that the gene, like sex, is not primitive; nor is its alleged stability a fact.

Pertinent to the fallacy of genetics as a physical science is my own senior thesis dated 1909 (Minnesota) on "The Cytology of Weismannism." This paper not only rejected the mutation-selection theory in almost the same terms as those of Dr. Martin's treatise of 1956, but in a full review of the evidence in the literature of genetic cytology, nucleic acid was twice mentioned as playing some part in the processes of heredity. Though this theme of the early twentieth century is "dated" in some particulars, there is no more reason now than there was then to believe, with Sinsheimer, that "this hard-won recognition of the role of DNA (nucleic acid) has brought us into a new era in genetics and biochemistry. The gene, once a formal abstraction," he concludes, "has begun to condense, to assume form and structure and defined reactivity."

That this is wishful thinking; that there is nothing new in the evidence at hand today which can change the conviction that a chemical explanation of life can never be adduced, can be seen by comparing the two papers. So that interested readers may do so, "The Cytology of Weismannism" is here submitted for its first printing.

To predict by extrapolation from statistical correlations is the unforgivable sin of biological empiricism. There are some contexts in medical practice having legalistic implications, where statistically "educated guesses" as to "calculated risks" form the basis of "expert" opinion used, for example, in judging degrees of disability and causes thereof, as in insurance payments, suits for damages, social "security", veterans compensation, and the like. But in a social context where the results of taking chances with probability are compounded by a multiplier or even exponentially, as in public health policies or in the anarchy of foreign relations where victory or defeat in global warfare is the risk involved, its success, if any, is at best illusory and its failure catastrophic. Biologicaly and culturally Operations Research is worse than futile; it is fraudulent. In medical practice or research epidemiological figures can at best furnish only clues, never evidence that confirms any hypothesis. If the patient is going to die anyway—a fix in which everyone finds himself sooner or later—an experiment may be in order. But when the fate of a people is in the balance and survival is at stake, in disarmament schemes for instance, or when the health of millions of children is concerned with the standardizing of a vaccine, then a trust in statistical probability as against a laissez faire policy, can be disastrous.

Such an error has just been courageously exposed, even in Science (May 31, 1957), namely, the fiction of the safety of the Salk polio vaccine; nor is this the first Nobel Prize in medicine that has not been rescinded in the light of the pitiless truth as to its falsity. In this exposure of the untruths broadcast by the National Foundation for Infantile Paralysis, falsehoods which are plainly proclaimed, there is a serious omission in failing to state the underlying occasion for them, to wit, the idea that the degree of probability can be scientifically measured in biology as in physics and make (to quote the DuShane editorial on dice again) "the phrase 'calculated risk' * * * mean something a good deal more precise than the 'best guess'," and afford a reliable basis for a public policy based on "appropriate statistical and epidemiological studies."

That hundreds of children were not paralyzed and crippled, or even killed, was the work, not of medical science, but of nature; for had the same children been vaccinated with unattenuated virus very few clinical cases would have developed. The probability that infection will cause the disease is so low that its incidence cannot be taken as a measure of the spread of the virus. Poliomyelitis is a relatively rare disease; so also is leukemia. Vaccines for all such afflictions—and they are multifarious and but dimly classified—would burden the community beyond endurance if promoted as a public charity. The treatment of hog chlorea by a similarly attenuated, living vaccine has admittedly kept the disease active instead of exterminating it; so at long last the live

vaccine is being eliminated by law. It has been unjustified also in poliomyelitis, despite the full responsibility of the National Institutes of Health for promoting its use.

The logical fallacy of statistical biology with its reliance on correlations can be shown by an "anthropomorphic" analogy such as was banned from Tennessee public schools by law and, right now, is "scientifically" tabooed by the "positivistic" ban on "anthropomorphic extrapolations."

The cultural DNA of modern civilzation is plainly *money*. That it is coined from gold and other "precious" metals is as irrelevant to its value as an informational guide for human exchanges and consequent behavior, as is the forming of genes (genetic prices) from nucleotides. It is quite as absurd to believe that the substance of DNA must differ in its physical structure in order to create a man instead of a monkey, as it ever was to believe that an ovum is simply a small edition of an embryo and has only to grow to produce an adult man or monkey.

The assertion of Dr. Glass before the Committee that something like a template (a "mould" or "replica") is involved in the embryonic developmental process, is just this sort of untenable belief for which there is no evidence at all. At fault is, basically, the treatment of "information" as a matter of signals as distinguished from signs or symbols with a metaphysically conditioned system of meaning. It is not at all necessary for the same word (or figure) to be used to convey the same meaning (or value); nor different words to appear when different meanings are conveyed. Ambiguity is rampant in language—as are paradoxes in mathematics. An assumption that there is a similar dialectic in genetics constitutes the only possible alternative for the empirical ambiguities which must be eliminated from science by sound reasoning from realistic principles.

The composition of chromosones, genes, alleles, genomes, nucleotides—or what-have-you in genetic equipment—can never determine what they signify in the organism's behavior and development, just as monetary units of various denominations cannot determine the real values underlying the judgments and consequent behavior of a business community as guided by intelligence (price relations); the values are the same regardless of the prices which the number of dollars or pounds determines. *Changing* prices do distort the normal course of judgment and action just as ambiguity distorts the influence of speech or literature in behavior. The fact that it is an artifice, not a reality, that creates the uncertainty of meaning and of biological behavior in general through *conditioned* reflexes (learned symbols) is the essence of the problem of living together by communicated information. There are no puns or paradoxes in nature's realities.

If a Man from Mars were to observe the number of pounds in a British pocket, and the number of dollars in a Canadian pocket, he would have no way of knowing that they differ in their value even though they look alike. So if he were to use Cartesian coordinates in two dimensions to correlate these numbers with the energy level of observed events (behavior) related to those numbers, would he be warranted in "discovering" that this graphic relation is a natural constant? What should he conclude if the British set up another Newtonian Recoinage Commission, or if an International Monetary Fund changed its "mind" on the proper exchange rate, so that the energy level of events departed from the previously observed, linear correlation? Should he call it a "spontaneous" mutation? Would not some Martian jester turn up to publish a report in a Saturnian Science on the rhythmic clock of *Unicornus martius*?

Of Dr. Bentley Glass discovers (as he has) that the correlation between the traits of *Homo insipiens* and the number of chromosomes is not 48 after all, shall he conclude that all the observers who counted 48 were cross-eyed, or that their staining techniques were defective? Or should he conclude, with an ancient inscription in the Libyan Desert, that "Life is change; to cease to change is to cease to live"? If the nucleotides-to-be-counted with electronic relays when genetic chemistry gets a big enough appropriation to buy a big enough computer from IBM, turn out, as all such research to date has done, only some more negative results in the attempt to correlate their chemistry with their behavior in heredity, will it at long last become reasonable to agree with Dr. Lindegren that genes are not stable after all? Will it finally be admitted that his charge that the evidence of such stability has been a matter of choosing only data that support such an assumption, is warranted?

The loophole in the "laws" of Mendelian inheritance as presented by the geneticists before this Committee, lies in their manipulation of "spontaneous"

cases of genetic change to avoid admitting that any of them are adaptive. Adaptation has been ruled out of the vocabulary of organic evolution so that life is today supposed to be one grand symbiotic brotherhood seeking a communistic goal in selfless abandon. Perish the thought of conflict of purposes acting incompatibly in a tooth-and-claw struggle, or of any innovation in survival that has been other than the result of rare accidents in throwing genetic dice that are *not* loaded! Those big claws on Alaskan king crabs turned pink by our loving kindness, are purely ornamental, love-patting appendages, swords beaten into plow shares like atoms-for-peace in Utopia.

The dispute in these hearings over the interpretation of data has hinged on the idea of a threshold as opposed to linear extrapolation, rather than on the evidence that has here been adduced as to the absence of biological constancy where genetic science has postulated it. What remains to be shown, therefore, is that nature consists of thresholds, not of linear correlations, and that research consists of discovering the status of thresholds, never in tracing imaginary linear relations. This would be obvious but for the linear predilections of the Euclidean influence in science for even in the inorganic realm of physics the field of macrocosmic relations is not universal; witness phase transformations such as melting points and boiling points and their energy relations. A jet plane passes from one range of speed into another with an explosive sound as it crosses the "barrier" into a very different set of relations. Physical constants established by instrumental measurements (as by the National Bureau of Standards), such as those of Hooke's Law on the strength of materials, which are inapplicable to very small sizes such as exist in one of the most recent developments in solid state physics (metallic "whiskers"), are another example.

In biology the operation of sensory perception, from which all knowledge proceeds, is replete with thresholds. The *source* of knowledge is the same for any and all of the creatures that inhabit the earth; it lies in a myriad of wave forms, or bands, filling all possible environments throughout the universe. But there are great areas of this spectral information that are extrasensory for any mammal. Some bands are accessible to insects but not to vertibrates; and some mammals such as rats, bats, cats, dogs, can sense ranges greater or less than other species, man included. Some men can sense a range wider than others; but none can be devoid of all sensation and still live.

Other sensations can be translated into tactual perception, as by Braille, to make individuals "literate", that is, to train their reflexes for communication purposes in guiding behavior. In this aspect of a cultural heritage as it operates genetically—and genocidally—in the human struggle to survive, telecommunication preforms transformations in and out of sensory ranges, with continual improvements for technically conditioned people.

Thus science as we know it is continually extending the range of sensation and communication to new bands and ranges; but these new, extrasensory signals have to be modulated into the normal sensory ranges or thresholds before they can affect behavior. No possible information can be had without reference to these physical wave bands as they have been affected by discontinuities (things) in the pyhsical universe. It is because the laws governing these spectral conditions never change anywhere in eternity, so that the sequence of events they reveal is absolute, that time cannot be reversed or events known that have not yet occurred. (Cf. Anthony Standen on "Causes and Effects" in Science, May 3, 1957, p. 900.) Thus no possible living creature can have any information available for conditioning its reflexes (guiding its behavior) that does not rest on these ordered discontinuities (waves and particles), in the physical environment, that are the source of all certainty in sensory experience.

But if sensory equipment has its thresholds, living conditions are also narrowly restricted to those prevailing in the so-called biosphere. Some heat is essential; much more or less, is lethal. It's a case of not crossing a *threshold* and getting *too much* of the good things of life; including life itself. To avoid too much or too little, animals have evolved sensory equipment which men are still evolving by mechanical instrumentation which facilitates motility and thus also serves predatory purposes in acquiring food. Then there are the "trace" elements, essential to plant growth, an excess of which is toxic. In short, there is no such thing as a "linear" relation between life and the elemental forms of matter and energy. A threshold is the very essence of life.

Linear projections or extrapolations are a semantic fiction originating in the Euclidean concepts that arose in the days when the earth was called flat and everything in geometry was worked out in terms of rectilinear and rectangular frames of reference, a state of affairs that still plagues the problems of solid state physics. Molecular engineering, such as is characteristic of this atomic age,

cannot be conducted in these all too familiar terms. The microcosm, in short, is not at all a replica of the macrocosm, as it was held to be by no less a scientist than Thomas Huxley, father of the equally mistaken geneticist, Julian Huxley. This false analogy is being gradually abandoned though the layman is still deluded by the clutter of orbits in pictures of a now discarded concept of the behavior of electrons in an atom. "Shells" (energy "levels") have become the "truth"; and just now there seems a prospect that "spin" will also be displaced, perhaps by a helical structure. The whole theory of atomic and molecular models seems to be in a highly fluid state of uncertainty that is semantic rather than realistic in character. The meaning of symbols, such as the linear representations of Euclidean geometry, is at stake.

The truth about mathematical semantics seems to be that the so-called "natural" numbers, said to be an infinite continuum, are actually *un*natural in being a progression from an arbitrary origin (zero) in two "linear" directions. When they represent objective measurements of physical realities (rather than "value judgments" which can never be referred to any standard, subjective unit to give commutative character to their meaning) they are dimensional and, however remotely derived by instrumentation, they do form an integrated whole or system through reference to the ultimate unit, an arbitrary standard of length, to wit, the yardstick at the National Bureau of Standards. The resulting figures, called measurements, are always, whether "first" or last, approximations and never fully commensurable.

Truly *natural* numbers are dimension*less*; they have no quantitative meaning. Their field seem to be derived from the symmetries of microcosmic, spherical packing which emerge into specific forms in the periodic table of elements and in crystalline structures. Their order, if any, is timeless and independent of any comparison in size and they omit all but the smallest prime numbers since they are exponential and are not amenable to decimal treatment. No zero, no signs (plus or minus), no incommensurables, approximations or probabilities, no statistical averages, are involved in these symmetrical realities that never signify values either measured or subjectively appraised. Incidentally, it is not true that ratios are independent of dimensional numbers.

Assuredly, these venturesome generalizations need to be as critically reviewed as do the accepted conventionalities of mathematics. They are entered here heuristically, to suggest a clear distinction between certainty and uncertainty, a definitive difference between the possible and the impossible, in order to realize that the element of uncertainty is injected as soon as the information existing in the microcosm is "perceived," that is, *after* the optical structure of the eye, for example, has detected the signals and started, not merely to amplify, but to "comprehend" or classify them relative to the purposive procedures implicit in the neural system of any animal, such as a man or an insect. From then on there is a degree of uncertainty paralleling the logical doubt as to the truth of such semantic signs as are used in communication, even by honeybees.

There is nothing more irrational than the bland assumption that what is not yet known to exist must be considered not to exist, scientifically speaking. As Professor Ballard of Tulane University expresses this in the July, 1955, issue of Philosophy of Science, there is every reason to suspect that a dialectic comparable to human (and apian) language is "also carried on within an individual between distinguishable parts of his organism," a phenomenon which obviously presents "metaphysical" aspects and therefore "problems which mechanics cannot solve." Explanations which are a matter of inference by analogy, and not a matter of observation psychologically, thus lose their aura of mysticism and become scientifically anti-empirical. Rational strategy often rests, not on experimental verification of a suspicion (hypothesis) but on an "anthropomorphic" inference or belief that *all* behavior derives from communicated intelligence; subconscious action (instinctive) is not altogether mechanistic or free from awareness, not even in hereditary phenomena.

So meaning in communication is metaphysically incorporated and only approximately true at "best", while at "worst" (these antitheses are reversible in their "value" judgment, depending on whose ox is being gored) it is deliberately deceptive in its strategy, even though only by the "humor" of a pun. The living, purposeful organism has to learn not to be naive but to correct such illusions as that of the asymptotic approach in the perspective of distance or that of change in the pitch of a sound as its source moves past to create a "Doppler effect."

Dr. Schweitzer to the contrary notwithstanding, John Gunther's medical treatise on cancer and death is grounded on falsehood; for it is Life, not Death,

that needs to "Be Not Proud!" Immortality is impossible. Racial survival is possible, but not certain. Indeed, it too is impossible if all life—all mankind—is to be the objective. A Communistic Utopia is entirely outside the pale of any Creation except that of a demagogic imagination. Humility toward our competitors (our "fellow men") can only be hypocritical. Only the Creator (if any; we can never know), or better the actual order of the universe (which is not beneficent but is the very paradigm of neutrality) can be an object of respect and faith on the part of any moral culture seeking a political order not grounded on the personal discretion of leadership (der Feuhrerprinzip) in determining its blindfolded justice.

Occasionally the life of the individual can and must be treated with the utter *sang froid* of statistical probability and war, for it is always subordinate to the higher order that can be immortal. We can be legally exempt from taxes, but not from death. The termination of the life cycle can only be postponed, even by "Atoms in Our Future," the pleasant author of this pleasant prophesy, Senator Anderson, to the contrary notwithstanding. Men may be blessed with "travel out among the stars" and "pushbutton weather" (which is not altogether lacking even in New Mexico without benefit of atomic energy). But any promise of "even eternal life" is out of the reach of either man or God or, even, of the Positivism of such "science" as that which Sir George Thompson has set forth *ex cathedra* in his "The Foreseeable Future."

In her youth Lily Pons popularized "I Dream Too Much!" Perhaps her vibrant voice could yet teach it to Sir George and the prophetic Senator and persuade them and their sycophants in science to think in terms of thresholds rather than extrapolations.

Radioactive Fallout

Selected List of References

(Prepared by Ruth A. Little, Legislative Reference Service, Library of Congress, June 30, 1957)

Bibliographies

Argonne National Laboratory, Chicago, Ill. Annotated bibliography in radiobiology, by Sophie V. Stephens and Robert D. Boche. Chicago, Ill., 1953. 367 pp. (ANL–5111).

Bibliography containing 2,153 abstracts covering all phases of the biological effects of radiation.

Available from Office of Technical Services, United States Department of Commerce.

——— ——— The tolerance dose, by S. T. Cantril and H. M. Parker. Chicago, Ill., January 5, 1945. 23 pp. (MDDC–1100).

Atomic Bomb Casualty Commission. Bibliography of A-bomb material collected through April 17, 1952. Washington, D. C., 1952. 27 pp. (AEC File No. NP–4563).

List of 124 references covering both published and unpublished material on the effects of the atomic explosions at Hiroshima and Nagasaki.

Battelle Memorial Institute, Columbus, Ohio. A bibliography on "The effects of X-rays on bacteria," by R. F. Robinson [and others]. Columbus, Ohio, August 20, 1951. 18 pp. (AEC File No. NP–3610).

Includes published articles from 1896 through August 1951.

Brookhaven National Laboratory, Upton, N. Y. Conference on biological applications of nuclear physics, July 12–27, 1948. Upton, N. Y., 1948. 154 pp. (BNL–C–4).

Summary paper covering biological effects of radiations. Documented by lists of references.

——— ——— Effects of radiations on biological systems, by A. H. Sparrow and B. A. Rubin. Upton, N. Y., February 15, 1951. 94 pp. (BNL–97; AECU–1207).

California. University. University at Los Angeles. Atomic Energy Project. Recent attempts to alter the response to ionizing radiations, by Wilbur A. Selle [and others]. Los Angeles, Calif., September 15, 1953. 73 pp. (UCLA–264).

Previous reports reviewing literature dealing with attempts to alter the response of animals to ionizing radiations were published in 1949 and 1951. This report summarizes 118 additional papers published 1951 to 1953.

Carbide & Carbon Chemicals Co., New York, N. Y. Literature survey on skin decontamination, unclassified material, by Francis L. Sachs. New York, 1951. 2 parts.

Part II, 22 pp. (Y–B4–4).

Part III, 23 pp. (Y–B4–10).

——— ——— Radiation effects on the blood, by Francis L. Sachs. New York, July 23, 1951. 11 pp. (Y–B4–22).

Bibliography containing 51 titles selected from Nuclear Science Abstracts.

——— ——— Preliminary literature survey on skin decontamination, unclassified material, by Francis L. Sachs. New York, March 1, 1951. 10 pp. (M–4638; TEM–12317).

——— ——— Skin decontamination; a literature search, by Francis L. Sachs, New York, October 22, 1952. 26 pp. (Y–914).

63 annotated references on skin decontamination, radiation protection and treatment of radiation injuries.

Chicago. University. Metallurgical Laboratory. The effects of X-rays on immunity, by W. H. Taliaferro and L. G. Taliaferro. Chicago, Ill., June 1946. 42 pp. (CH-3891).

Survey of X-irradiation effects on: formation of specific antibodies after immunization with nonliving antigens; infection with animal parasites; infection with bacteria and viruses; and mechanisms of radiation effects in the host. 158 references.

Great Britain. Atomic Energy Research Establishment. Range-energy and range-momentum relationships for charged particles; a bibliography. Harwell, Berkshire, England, February 1951. 27 pp. (AERE-Inf/Bib-71).

222 references.

——— ——— Some papers on the effects of radiations of bacteria and moulds. Harwell, Berkshire, England, October 14, 1949. 7 pp. (AERE-Inf/Bib-51).

List of 69 papers covering 1930 to 1949.

——— ——— Some published reports on the effects of radiation on reproduction and on the genetic effects of radiation, by A. Lundie. Harwell, Berkshire, England, March 8, 1950. 10 pp. (AERE-Inf/Bib-61).

List of 69 references.

List, Robert J. Annotated bibliography on the transport and deposition of atomic debris. Washington, United States Government Printing Office, 1956. 27 pp. (U. S. Atomic Energy Commission TID-3061).

National Research Council. Division of Medical Sciences. Conference on radiation cataracts and neutron effects, by Philip H. Abelson. Washington, D. C., February 17, 1950. 100 pp. (AEC File no. NP-1826).

Report on the conference, composed of two parts: (1) a discussion of the production and detection of neutrons and of experimental neutron-irradiation of animals and (2) a discussion of various studies made on the lens of the eye and the effects of radiation thereon. 181 references.

Oak Ridge National Laboratory, Oak Ridge, Tenn. Bibliography of unclassified documents. Oak Ridge, Tenn., n. d. 10 pp. (ORNL-502, pt. 2).

Documents included cover the biological and medical aspects of radiation; radiation protection and health physics; and inhalation of toxic and radioactive materials.

United States Army Medical Research Laboratory, Fort Knox, Ky. Adaptation to ionizing radiation, by A. T. Krebs and John B. Storer. Fort Knox, Ky., February 2, 1955. 17 pp. (AMRL-175).

Reviews literature on radioresistance in mammalian systems. 40 references.

United States Atomic Energy Commission. Civil defense against atomic warfare; a selected reading list. Washington, D. C., United States Government Printing Office, March 1950. 24 pp.

List of references on radiation detection, protection and biological effects. Divided into USAEC and other Government agency reports.

Examines the role of the soil in limiting the spread of contamination.

———. Soil chemistry and the uptake of fission products. Research (London), v. 8, 1955: 335–340.

Traces the likely fate of radioactive contamination from an atomic bomb explosion or a nuclear reactor accident according to the nature of the ground contaminated, and discusses possible treatments of contaminated land.

Anderson, E. C., and others. Radioactivity of people and foods. Sciences, v. 125, June 28, 1957: 1273–1278.

Andrews, Howard L. Radioactive fallout from bomb clouds. Science, v. 122, September 9, 1955: 453–456.

General discussion of radioactive fallout in the vicinity of nuclear detonations, including mechanics of formation, amount of activity, etc. Discusses maximum permissible levels of gamma radiation for test series, estimates dosages near test site under certain assumptions. Discusses beta burn hazard and danger from retention of particles in lungs. Concludes only particles from 0.5 to 5 micron diameter are potentially hazardous to lungs, and fraction in this size range will be small. Also discusses long-lived fallout and potential hazard from Sr–90 and genetic effects. Concludes weapon testing program justified by defense effort and that radiological hazards have been minimized under the well-controlled conditions of weapon testing.

Answer sought to fallout hazards. Chemical and engineering news, v. 33, April 25, 1955: 1774.

Coven, A. W. Evidence of increased radioactivity of the atmosphere after the atomic bomb test in New Mexico. Physical review, v. 68, 1945: 279.

A G.-M. counter and circuit (Rev. Sci. Instr. 13, 188 (1942)) was tested for background count near Annapolis, on July 12, 14, 15, 19, August 16 and October 31–November 3, all in 1945. The background count was 5.5 per minute. On July 16–18 the background count was 6.3, 7.7, and 10.7 per minute, respectively.

Cronkite, Eugene P., and others. Biological effect of atomic bomb gamma radiation. Science, v. 122, July 22, 1955: 148–150.

Mice were exposed to atomic bomb radiation at 28 stations no both sides of the established L. D. $_{50}$ distance to compare the biological effect with that produced by laboratory gamma and X-radiations. At doses up to 620 r, mortality was consistently at 3 percent but above this dosage, mortality increased rapidly to 950 r, which was approximately the absolute lethal dose. The established L. D. $_{50}$ was 759 r. The relative biological effects of X-ray to bomb radiation closely approached unity.

Cronkite, Eugene P., and others. The characteristics of fallout material and the effects of fallout radiation on human beings. Radiation research, v. 3., No. 2, 1955. Presented before the Radiation Research Society, New York, May 16–18, 1955.

Human beings were accidentally exposed to fallout radiation commencing approximately 5 hours after explosion of a large nuclear device. The fallout material was visible (snowlike). It contaminated skin, clothes, and surroundings, producing skin lesions, whole-body effects, and internal deposition of small amounts of radionuclides. Whole-body exposure occurred at four levels: 175 r, 78 r, 69 r, and 14 r midline dose of radiation.

Damon, P. E. and Kuroda, P. K. Artificial radioactivity of rainfall. Nucleonics, v. 11, December 1953: 59.

Fission products found in rain water during the period June 5–July 23, 1953, correlated with the origin of the prevailing air mass. The total fission activity fallout in the vicinity of Fayetteville, Ark., during this period was in excess of 10^{-8} curies per square mile.

Disposal and dispersal of radioactive wastes. Science, v. 124, July 6, 1956: 17–19. Part of National Academy of Sciences report.

Dunn, L. C. Radiation and genetics. Scientific monthly, v. 84, Jan. 1957: 6–10.

Dunning, Gordon M. Effects of nuclear weapons testing. Scientific monthly, v. 81, December 1955: 265–270.

Presents a summary of blast, thermal and radiation effects of atomic testing. Discusses internal radiation hazard from radioactive iodine, strontium and carbon hazard from contaminated foods. Concludes hazard negligible to date. Discusses genetic effects and possible increase in mutations. Computes the average radiation exposure to people in the United States from all nuclear detonations to date is 0.1 roentgen. Discusses possible effects on weather and nitric acid formation and concludes effect is negligible.

———. Monitoring network for measuring radioactive fallout. Journal of the American Water Works Association, v. 48, 1956: 659–664.

The basic mechanics of radioactive fallout are discussed. The principal isotopes are listed, collection stations are tabulated, and methods of analysis are briefly outlined. The isotope Sr^{90} is considered the constituent of prime biological significance.

——— and Harley, John H. Radioactive dust from nuclear detonations. Science, v. 117, February 13, 1953: 141–147.

A network of 121 monitoring stations has been established in the United States to collect airborne and settled dust samples for radioactive assay. The results from 30,000 samples collected in conjunction with the 8 detonations in Nevada between April 1 and June 4, 1953, are given. For brief periods following an explosion the radioactive background can be increased in distant areas by fallout of airborne dust.

——— and Harley, John H. Radioactive fallout in the United States. Science, v. 121, May 13, 1955: 677–680.

Summarizes fallout in the United States from early in 1951 through 1954. Accumulated fission product activity in the United States, exclusive of the area within 200 miles of the Nevada test site, was 61 millicuries per square mile. Gamma radiation from this is of the order of 0.0010 mr/hr compared with normal background of 0.005 to 0.05 mr/hr. Measuring technique detects increase of 10^{-8} roentgens per hour, natural background 5×10^{-6} to 5×10^{-5} r/hr.

Eliassen, Rolf and Lauderdale, Robert A. Radioactive fallout in water supply at Portland, Maine. Journal of the American Water Works Association, v. 48, 1956: 665–670.

This work was done to determine any radioactive increase following atomic weapons tests during 1955. Nine objectives are outlined. Analytical procedures are listed, and the results discussed. Materials of all kinds were

found. It was found that Sr^{90} in the tap water could be increased by a factor of about 70,000 before exceeding the limits specified by the National Bureau of Standards.

Fafarman A. and Shamos, M. H. Effect of fallout from atomic blast on background counting rate. Nucleonics, v. 11, June 1953: 80–81.

Background measurements with a sodium-iodide scintillation detector at New York University show normal variation of ±5 percent. At 1030, March 19, 1953, the rate increased to 3850 cpm, 600 percent above background. A heavy rain preceded the measurement and presumably contained debris from the March 17 Nevada test. Removal of rainwater dropped rate to 1470 cpm. Curves of energy versus count before and after fallout are given.

Fallout detector. Military review, v. 35, March 1956; 69.

Fearson, R. E., and others. Results of atmospheric analyses done at Tulsa, Okla., during the period neighboring the time of the second Bikini atomic bomb test. Physical review, v. 70, October 1 and 15, 1946: 564.

Radioactive concentrates were prepared from the atmosphere. Data of July 26 and August 30, 1946, represent the active deposits of Rn and Tn. The data of July 28, based on two samples with initial intensities of $\sim 5 \times 10^{-10}$ curie, are explained by assuming that the concentrate is the active deposit of a new rare radioactive gas of at. No. 86, with a halflife of 82 min.; it corresponds with at least two members of an unreported radioactive series.

Fields, P. R., and others. Transplutonium elements in themonuclear test debris. Physical review, v. 102, 1956: 180–182.

The isotopes of curium, berkelium, and californium found in the thermonuclear debris of the November 1952 thermonuclear test are discussed. The instantaneous buildup of the heavy elements in the thermonuclear device is compared with the buildup during pile irradiation. The alpha-particle energy (5.4 Mev) and the spontaneous fission half-life ($<1.2 \times 10^7$ years) of Cm^{246} are reported. The spontaneous fission halflife of Cf^{254} was found to be 55 days. No other mode of decay was observed for this isotope.

Genetic effects of atomic radiation. Science, v. 123, June 29, 1956: 1157–1164.

Text of the summary report of the Committee on Genetic Effects of Atomic Radiation, one of six reports prepared for the Study of the Biological Effects of Atomic Radiation by the National Academy of Sciences.

Genetics and the atom. Bulletin of the atomic scientists, v. 11, November 1955: 314–343.

Issue contains an editorial on genetics in Geneva, glossary of genetic terms and articles on the subject.

Greenfield, S. M. Ionization of radioactive particles in the free air. Journal of geophysical research, v. 61, 1956: 27–33.

In order to evaluate the possible role of radioactive particles from an atomic cloud as condensation nuclei, an analysis has been made to determine their degree of ionization. Individual radioactive particles become ionized owing to β-emission, and an estimate of the half-life of these ions has been made for various times in the life history of an atomic cloud. It is concluded that while there is a transient charge on these particles, its half-life is small compared to the disintegration rate, with the result that for all practical purposes radioactive particles in the free air are not necessarily preferred condensation nuclei.

Haldane, J. B. S. Genetical effects of radiation from products of nuclear explosions. Nature, (London) v. 176, July 16, 1955: 115.

The serious nature of genetical effects of radiation is argued. Upper and lower limits of radiation-induced human mortality are estimated.

Harris, D. Lee. Effects of atomic explosions on the frequency of tornadoes in the United States. Monthly weather review, v. 82, December 1954: 360–369.
The increase in tornadoes reported in the United States during the past few years is ascribed to better reporting procedures rather than the presence of atomic debris. Maps showing the distribution of fallout in the United States during the first and second halves of May 1953 are given.

Harris, William B., and LeVine, Harris D. Sampling and measurement of radioactive atmospheric pollution. Proceedings of the Air Pollution Control Association, 1953: 17–21.
Apparatus is described for continuously monitoring the alpha and gamma radiation from stack effluents. A storage-battery-driven dust collector can be used to collect dust away from power sources. An adhesive-coated film can be used to collect "fallout," at a distance from the source. An apparatus is shown for collecting samples nearer the source of contamination by the use of impactors, cyclones, etc.

Harris, D. Lee. Effects of radioactive debris from nuclear explosions on electrical conductivity of lower atmosphere. Journal of geophysical research, v. 60, March 1955: 45–52.
An increase in the ionization near the ground due to the fallout from a radioactive cloud formed by a nuclear explosion will increase the conductivity and lower the potential gradient in the lower atmosphere. Records of atmospheric conductivity and potential gradient from the Tucson Magnetic Observatory are compared with records of the deposition of atomic debris on the ground following the Nevada tests.

Herzog, G. Gamma-ray anomaly following the atomic bomb test of July 1, 1946. Physical review, v. 70, 1946: 227–228.
A recording gamma-ray meter (in Houston, Tex.) indicated a peak in atmospheric gamma rays, from 8 p. m., July 4 to 7 p. m., July 5, with a maximum at 3 a. m., July 5. The maximum increase was 77 percent of the background count.

Heslep, J. M., and Bellamy, A. W. Sampling for airborne radioactivity. Air repair, v. 5, May 1955: 1–4.
Potential sources of radioactive aerosols are discussed, and special attention is given to widespread contamination as might be expected from atomic weapons. There is no perfect sampling method, but rather good results have been secured by use of con. vacuum cleaners and Hollingsworth and Vose H–70 filter paper. Particle-size determinations are best made by the cascade impactor—this gives good characterization of particle size down to 0.3–0.6 μ

Hess, Victor F. and Luger, Paul. The ionization of the atmosphere in the New York area before and after the Bikini atom-bomb test. Physical review, v. 70, 1946; 564–565.
From June 29 through July 10, 1946, no atmospheric ionization due to the atomic bomb was observed.

Hollaender, Alexander. Modification of radiation response. Bulletin of the atomic scientists, v. 12, March 1956: 76–80.

Holzman, B. The effects of atomic bomb explosions on weather. Weatherwise, v. 4, February 1951: 3–4 f.

Holter, N. J. and Glasscock, W. R. Tracing nuclear explosions. Nucleonics, v. 10, August 1952: 10–13.
Airborne radioactivity precipitated in rain and snow has been measured by counter observations on samples concentrated by evaporation or filtration through cotton. A maximum half life of 10.6 hours (Pb^{212}) is associated with natural atomspheric activity. A number of samples collected (at Helena, Mont.) revealed activities of much longer decay periods. These are attributed to atomic explosions in Nevada and Russia. It is considered possible to assign a date to the occurrence of the explosion from observations of the decay curve.

Humphrey, Andrew J. Radiation injury: a technical and legal survey. Cleveland—Marshall law review, v. 6, May 1957: 171–188.
Examines the relations between various types of radiation as to sources and effects.

Hunter, H. F. and Ballou, N. E. Fission-product decay rates. Nucleonics, v. 9, November 1951: C-2–C7.

Jaffee, Gilbert, and others. Radioactive hailstones in the District of Columbia, May 26, 1953. Bulletin of the American Meteorological Society, v. 35, June 1954: 245–249.

At 2030 Greenwich civil time on May 26, 1953, hailstones ranging to the size of tennis balls fell in the District of Columbia, 29 hours after an atomic test in Nevada. Activity of 620 c/m as compared to a background of 20 c/m was measured in the stones. Meteorological analysis and decay curves confirmed the origin of the radioactivity as being from the atomic test.

Kellogg, D. A. Atomic defense in oil refinery. Petroleum engineering, v. 27, October 1955: C6–C8.

Methods of preventing continuous effects of radioactive fallout.

Kellogg, W. W., and others. Close-in fallout. Journal of meteorology, v. 14, February 1957: 1–8.

Keosian, John. Speculation on hazards of exposure to radiations. Science, v. 122, September 30, 1955: 586–587.

Question of maximum tolerance dose of radiation for man has not been satisfactorily determined. It may turn out that all high energy radiation, even of low intensity and brief duration must be considered as potentially dangerous to the exposed individual.

Kilcawley, E. J. Measurement of radioactive fallout in reservoirs. Journal of the American Water Works Association, v. 46, November 1954: 1101–1111.

An extensive survey of radioactivity in the Troy, Albany, Schenectady water supply system was made in an investigation following the heavy rainout which occurred in that area on April 26, 1953. Samples of water, soil, algae, plants, etc., were measured for radioactivity. Decay rates, effectiveness of filtration, rate of disappearance, etc., were studied. The general contamination of the ground at arrival time was 1μc/ft^2. Surface water at Rensselaer Polytechnic Institute, Troy, N. Y., had 2.7 x 10^{-2} $\mu\mu$c/ml. Measurements were also made for subsequent bursts. Corrected to time of rainout, highest rainwater activity was 25.0 $\mu\mu$c/ml on June 9, 1953. Highest stream samples, 0.10–.13 $\mu\mu$c/ml. Alpha activity of same samples was also investigated.

Libby, Willard F. Radioactive strontium fallout. Proceedings of the National Academy of Sciences, v. 42, June 1956: 365–390.

Based on a speech given before Annual General Meeting of the American Philosophical Society, April 20, 1956.

Hazards from Sr^{90} deposited in fallout following nuclear explosions are reviewed. $Strontium^{90}$ is of particular interest among the fission products because of chemical similarity to Ca, an average life of about 40 years, and a low rate of skeletal elimination. The maximum permissible average concentration of Sr^{90} in the adult skeleton is calculated to be 1μc/1,000 gm of Ca.

Data are summarized on Ca, Sr, and Sr^{90} concentration in samples of soil, animal, and plant material collected throughout the world before and after the thermonuclear explosions during Operation Castle. A Sr^{90} fallout probably derived from megaton weapons are nearly uniform over the world except for local effects due to rainfall variations and to fallout from submegaton weapons, was found to occur at least 1.7 years after the megaton test series. The average world-wide Sr^{90} fallout rate in the fall of 1954 and the spring and summer of 1955 was 1.2 mc/mi^2/yr. An estimate is presented of fallout rate of Sr^{90} to be expected from weapons tests up to and including the Castle series. Factors influencing the transfer of Sr^{90} from soil to plants, to animals and milk produced by them, and finally to the human skeleton are discussed.

Lieberman, Joseph A. Disposal of radioactive wastes—a growing problem. Civil engineering, v. 25, July 1955: 44–47.

List, Robert J. On the transport of atomic debris in the atmosphere. Bulletin of American Meteorological Society, v. 35, September 1954: 315–325.

Describes results of 91 gummed paper and 51 air filter monitoring stations in the United States during Nevada tests in the spring of 1952. Detailed meteorological trajectories of each of the bursts of the series are given, together with a discussion of the meteorological aspects of transport and fallout. Excluding area within 200 miles of test site, highest gummed paper fission product beta activity was 8×10^6 d/m/ft^2/day at station 330 miles from test side. At distances over 2,000 miles, maximum activity was 1.7×10^5 d/m/ft^2/day, on sampling day. The two highest air filter activities were 1.3×10^5 and 6.8×10^3 d/m/meter^3. Detailed discussion of fallout from 8 of the 8 bursts given, with daily maps showing isolines of activity and areas of precipitation for several days following the bursts.

———. On the transport of atomic debris in the atmosphere. Journal of the Air Pollution Control Association, v. 5, 1955: 153–156f.

The author correlated the meteorological trajectories of bomb debris following each of the eight nuclear detonations at the Nevada test site in 1952 with fallout in the United States. In most instances the predicted pattern of fallout was in agreement with fallout data.

Luntz, Jerome D. Radiation safety for a weapons test. Nucleonics, v. 10, May 1952: 10–13.

An eyewitness report on the elaborate system used to obtain detailed data on distribution of radioactivity from the atomic explosion on April 22, 1952.

Machta, L. and Harris, D. L. Effects of atomic explosions on weather. Science, v. 121, January 21, 1955: 75–81.

A study of temperature and rainfall for the United States does not indicate any departures from normal that are related to atomic explosions.

——— and Schlei, N. A. Hydrogen bomb tests in perspective: lawful measures for security. Yale law journal, v. 64, April 1955: 648–710.

Discusses conflicting claims of the security of the United States and its allies and the principles of international law as interpreted in some quarters.

Meinke, W. Wayne. Observations on radioactive snows at Ann Arbor, Mich. Science, v. 113, May 11, 1951: 545–546.

Rigorous chemical separations performed on radioactivities found in snows around Ann Arbor, Mich., after the Las Vegas atomic test explosions on January 27 to February 6, 1951, have definitely established the presence of radioactive rare-earth isotopes and Ba and/or Sr isotopes and have shown the possible presence of I isotopes. The tests conducted on the samples are described. Because of the chemical distribution of the activities found in the Ann Arbor snows, these activities undoubtedly originated in the Las Vegas atomic test explosions.

Nader, J. S., and others. Radioactive fallout in rain in the Cincinnati area. Journal of the American Water Works Association, v. 46, November 1954: 1096–1100.

Precipitation in the Cincinnati area was measured for suspended and soluble radioactivity from March 1953 to March 1954. "Background" level in precipitation was 0.03 to 0.08 $\mu\mu$c/ml. Maximum concentration, on April 29, 1953, 319 $\mu\mu$c/ml (500 $\mu\mu$c/ml corrected for decay). Maximum fall-out from a single rain on May 22, 1953, 1.55 inches containing 85.7 $\mu\mu$c/ml, giving 8.75 curies per square mile. Soluble activity averaged 60–80 percent of total before and after tests, fell to 30 percent during tests. Samples from creeks and tapwater show most of activity removed by natural purification. Accumulated and decayed rain activity on June 10 and December 10, 1953, was 2.4 and 0.15 curies per square mile, respectively.

Tajima, Eizo and Doke, Tadayoshi. Airborne radioactivity. Science, v. 123, February 10, 1956: 211–214.

Twenty-four hour air filters in Tokyo from March 16 to May 31, 1955, were measured for artificial and natural radioactivity. The samples consisted of 650 cubic meters per day and assuming a 10 percent collection efficiency of the Whatman No. 14 filter papers for small particles, the peak activity from fission products, observed on April 12, was $3 \times 10^{-15} \sim 1.2 \times 10^{-14}$ curies per liter, which is comparable to the concentration of natural activity. No consistent correlation of fission product activity with temperature was found and only a slight tendency for rainfall to clean the air was noted. A better correlation was observed with trajectories of high pressure areas.

Thomas, Harold A., and others. Radioactive fallout in Massachusetts surface waters. Journal of the American Water Works Association, v. 45, June 1953: 562–568.
Following the Nevada nuclear-weapons tests, tests were made in Massachusetts which showed a noticeable increase in radioactivity in rain falling. Results are tabulated and the presence of natural radioactivity is considered. On standing there seems to be a settling out of radioactive products.

Bond, V. P., and others. Hematological changes in human beings exposed to fallout radiation. Radiation research, v. 3, October 1955.
Presented before the Radiation Research Society, New York, May 16–18, 1955.

All individuals exposed to fallout radiation showed depression of the total white, lymphocyte, neutrophil, and platelet counts, more marked in the higher exposure groups. The total white count was consistently lowest during the sixth and seventh postexposure, followed by an upward trend. Six months after exposure, values for the highest exposure group had not returned to the levels of a control population comparable with respect to age and sex distributions.

Maher, Thomas F. Nature and significance of radioactive fallout. New England Journal of medicine, v. 252, 1955: 740–741.

Principal hazards of radioactivity produced by detonations of atomic weapons are I (half-life 11.5 days) and Sr (Half-life approximately 30 years). General protective measures that can be taken against radioactive fallout are shelter and decontamination, and the avoidance of ingestion or inhalation of contaminated mediums from the environment. Persons who have been exposed to radioactive fallout may show burns, hematologic and bone-marrow changes, and infection.

Technical Periodical Articles, Foreign

BRITISH

Auerbach, Charlotte. Biological hazards of nuclear and other radiations. Nature (London) v. 178, September 1, 1956: 453–454.
A comparison is made of British and United States reports on radiation hazards. Both reports show that the present dangers arise much more from excessive use of X-rays than from fallout or atomic energy establishments.
Biological effects of radiation. Nature (London) v. 179, April 13, 1957: 755–756.
Blifford, Irving H., and others. Relation between air concentration of radioactive fission products and fallout. Nature (London) v. 177, 1956: 990–992.
The daily atmospheric concentration and fallout of radioactivity due to fission products was measured at Washington, D. C., during December 1954–May 1955 by air-filter and gummed-paper techniques, respectively. The apparent rate of decay was used to distinguish between natural Th B and fission products. There was no correlation of individual daily measurements of air concentration and fallout of this material on the ground. Despite many variables the concept of fallout rate may be useful in arriving at some correlation.

———. Radiological hazards from nuclear explosions and nuclear power. Nature (London) v. 175, May 21, 1955: 873–875.

Reprint of address to the Parliamentary and Scientific Committee at the House of Commons, London, April 20, 1955.

Average concentration of radioactivity in the air at ground level over the last 3 years due to bomb explosions is about 1 percent of the natural radioactive dust content. Accumulated dose to completely unprotected people from fallout in England is about 0.01 R. Further fallout from airborne debris should bring it to 0.03 R. In the United States, average dose is about 0.1 R. Average dose in England to average person over a generation (30 years) will be about 0.003 R, natural radioactivity gives 3 R. Discusses other radiological hazards and concludes that probably at least 1,000 times the present level of contamination would be needed to give rise to serious harmful effects.

Sutton, G. Thermonuclear explosions and the weather. Nature (London) v. 175, February 19, 1955: 319–321.

Available evidence points to conclusion that atomic tests cannot be held responsible for any worldwide extremes of weather encountered in 1954.

FRENCH

Abribat, Marcel and Pouradier, Jacques. Evolution of the amount of artificial radioactive elements in the atmosphere of Paris. Comptes rendus, v. 237, 1953: 1233–1255 (in French).

The β-activities of airborne dust particles, rain waters, and natural waters were assayed daily between January and September 1953. The dust-particle activity showed 2 maximum March 24–June 25 and August 30–September 17, which probably resulted from atomic explosions in the United States and Russia, respectively. Rainwater activity gave only the earlier maximum while no changes in the activity of natural waters were found.

———, and others. Artificial radioactivity in rainwater of the Paris area. Comptes rendus v. 234, March 10, 1952: 1161–1163 (in French).

Considerable radioactivity was observed 8–15 days after the explosion of atomic bombs in Nevada.

——— ———. Evolution of atmospheric radioactivity in Paris region. Comptes rendus v. 240, 1953: 2310–2312 (in French).

Daily measurements of radioactivity have shown the passage of many atomic clouds, and particularly the series of explosions in the United States of America and Russia, while those in the Pacific and Australia have been identified in Milan. For the Australian explosion in October 1953 there was no radioactive increase in the air in the Paris region, while for the Pacific explosion there were measurable fluctuations but very feeble. For the Russian explosions in August 1954 the fluctuations were much greater than for the Pacific ones.

——— and others. On the artificial radioactive products present in the atmosphere in the region of Paris. Comptes rendus hebdomadaires des séances de l'Académie des Sciences (Paris) v. 235, July 16, 1952: 157–159(in French).

The radioactivity of solid matter in rain water and air collected near Paris in November 1951, and in April and May 1952, follows the same decay law as that observed for fission products after a nuclear detonation in Nevada in November 1951.

Bouquiaux, J. Ionizing radiations and public health problems. Archives Belges de médecine sociale, hygiéne, médecine du travail et médecine légale (Brussels). v. 14, May 1956: 230–268 (in French).

Garrigue, Hubert. The abnormal radioactivity of the atmosphere. Comptes rendus, v. 235, 1952: 1489–1499 (in French).

Further measurements on the radioactivity of the atmosphere near Puy de Dome are tabulated. The activity in April 1952 with a mean life of 25 hours was ascribed to the complex particles A. In June 1952 an activity with a mean life of 100–400 hours was attributed to the previously observed A″ particles. The activity associated with the A″ particles was also observed in the soil and air.

———. Atmospheric radioactivity of atomic origin. Comptes rendus, v. 237, November 16, 1953: 1232.

Aircraft measurements in October 1953, show at most, traces of radioactivity. Snow sample (7 kg) on November 3, 1953, yielded 0.1 x 10^{-13} curies/cm^3 (radon equivalent) in the residue, about 20 percent above background. Only β—activity was found.

———. Atmospheric radioactivity of atomic origin. Comptes rendus, v. 240, January 10, 1955: 178–180 (in French).

An improved collector has been installed in the aerial laboratory, but in recent months little activity caused by atomic explosions has been detected.

Garrigue, Hubert. Establishment of a flying laboratory and the improvement of apparatus for the study of weak radioactivity in the atmosphere. Comptes rendus, v. 230, June 26, 1950: 2279–2280 (in French).

Describes in general terms the equipment of a plane to measure the radioactivity of the air. The first flight, on May 13, 1950, showed a high concentration of natural activity and a measurable amount of activity of unknown origin with a long half-life.

———. Fresh outbreak of activity of atomic origin in the atmosphere. Comptes rendus, v. 240, 1955: 1453–1455 (in French).

During the period December 1954 to February 1955 values of the order of 1 β-emitting atom per cm^3 of air have been obtained for observations on the ground and in the air in Puy de Dôme region.

———. The invasion of radioactive air of atomic origin and its influence on atmospheric precipitation. Comptes rendus, v. 232, March 5, 1951: 1003–1004 (in French).

Reports on aircraft observations in June 1950 and in January and February 1951. On February 3, 1951, at 4,100 meters, a maximum concentration of 0.15×10^{-18} curies/cm^3 radon equivalent of material of 30–50 hour apparent half-life. Attempts to show that precipitation cleanses the tropospheric air.

———. Observations on the impurities in free air. Comptes rendus, v. 236, 1953: 2309–2311 (in French).

Results of analysis of atmospheric radioactivity and pollution from measurements on free air and on atomic precipitation (snow) at heights from ground level to the summit of the Puy de Dôme (1450 m) during January-February 1953. The radioactivity was probably of distant origin (from nuclear fission explosions); the dust and soot of local origin.

———. On the radioactivity of the atmosphere. Comptes rendus, v. 228, May 16, 1949: 1583–1584 (in French).

A radioactive substance with a half-life of 25 hours was detected in aircraft flights at about 6,000 meters in the summer of 1946 and again, in much weaker concentration, in the summer of 1948. Highest value reported, August 1, 1946, at 6,000 meters, 2.0×10^{-18} curies/cm^3. Observations at Puy-de-Dôme, 1,500 meters, gave no definite positive results. Speculation that material is from Bikini tests or possibly of meteoric or cosmic ray origin.

———. Prospecting the radioactivity of the air. Comptes rendus, v. 237, October 12, 1953: 802–803 (in French).

Measurements aboard an airplane (3,000 meters altitude) indicated a sudden influx of radioactive particles "A" with a mean life of 25 hours on August 8 (traces) and, in appreciable amounts, on August 15, 28, and September 5, 1953. The maximum of intensity of about 0.1×10^{-18} equivalent curie of Rn activity/cc. probably prevailed around August 15. No activity could be detected prior to these dates in air or in snow on the summit of Puy-de-Dôme (1,460 meters), nor did the evaporation of hail (collected on the ground), precipitated during a "microcyclone," which occurred on August 8, disclose any abnormal activity.

———. Radioactivity of the atmosphere of atomic origin. Comptes rendus, v. 237, 1953: 1232–1233.

Recent measurements at the summit of Puy-de-Dôme indicate the radioactivity of the snow may be attributed to atomic explosions.

———. Research on atmospheric radioactivity. Comptes rendus, v. 238, 1954: 2074–2075 (in French).

In flight at 2,800 meters, traces of radioactive particles were gathered by means of a corona effect similar to that of Sella, and of long period, on April 24, 1954. At Puy-de-Dôme (1,465 meters) after a fall of rain and snow on May 3–4, 1954, samples of the fallen residue showed very feeble radioactivity of period 10 days or more. This radioactivity of the airborne particles was independent of their probable natural electrical charge and mobility and was indicative of an atomic cloud.

———. Researches in radioactivity at the top of Puy-de-Dôme. Comptes rendus, v. 233, December 3, 1951: 1447–1448 (in French).

Snow collected at Puy-de-Dôme which fell on November 19–20, 1951, showed β-activity about 43 percent above background with an apparent half-life of 10 days. Speculation on role of particles as condensation nuclei.

———. Studies on the radioactivity of the atmosphere. Comptes rendus, v. 233 Oct. 15, 1951: 860–862 (in French).

The existence in the atmosphere of a radioactive substance, labeled "A," of several hours half life has been confirmed in flights at 3,300 meters, and at a ground station at 1,460 meters. Concentrations of Rn, Tn, "A," and "A'" observed from March 15 to August 14, 1951, are tabulated. The concentration of substance "A," of 20- to 30-hour half life, is related to atomic explosions and precipitation.

Lacassagne, A. Medical consequences of atomic bomb explosions. Bruxelles-Médical, (Brussels) v. 35, September 11, 1955: 1821–1833 (in French).

Martin, Charles Noel. Accumulative effects on the global surface caused by thermonuclear explosions. Comptes rendus, v. 239, 1954: 1287–1289.

HNO_3 is formed which locally lowers the pH of rain water. This can affect plant metabolism. C^{14} production and its absorption by living things is discussed.

Nahmias, M. E. Detection at a distance of atomic bomb tests. Mem. Artillerie Franc. 28, 1954: 393–402.

Nahmias describes the radioassay of atmospheric air, rain, and snowfall as the basis for detecting atomic bomb tests. Tables and graphs give time versus Ra equivalents, distance versus Roentgens/hours of radiation, and distribution of radio-elements which can be expected.

Ravina, A. The first known effects of hydrogen bomb on man. Presse médicale (Paris), v. 62, June 5, 1954: 881 (in French).

Tanaevsky, Olga and Vassy, Etienne. Variations of the natural and artificial radioactivity of the atmosphere. Comptes rendus, v. 241, 1955: 38–40.

The natural activity of the atmosphere, presumably Rn, Tn and their decay products, was most evident during periods of weak-winds at the Val Joyeux Scientific Station. In 30 of the 66 cases of high activity, the winds were from the southwest or west southwest, indicating a Rn source in that direction. The artificial radioactivity, detected in rains and snows, was strongest at the beginning of the precipitation. The highest activity measured was 0.724 microcuries/1.

GERMAN AND AUSTRIAN

Gerlach, Walther. The hazards of radiation and its danger to life. Universitas (Stuttgart, Germany), v. 2, 1957: 125–131.

Haxel, O., and Schumann, G. On the radioactive contamination of the atmosphere. Naturwissenshaften (Berlin), v. 40, 1953: 458 (in German).

Beginning on March 19, 1953, radioactivity in the air near Heidelberg was measured continuously by means of air filtering, using, in general, 48-hour exposures. The long-lived activity, presumably from atomic explosions, showed several peaks in the period from mid-March to mid-June, reaching a maximum of 2.5 curies/m^3 in mid-April. An examination of the decay rates allows the determination of the time of explosion. It was found that fission products reached Heidelberg in as little as 7 days from the Nevada test site.

Herbst, W., and others. Considerations of the suitability of radioactive atomic aerosols as tracers in meteorological flow investigations. Naturwissenschaften (Berlin) v. 41, 1954: 156–160 (in German).

A large increase in radiation from the ground at Wittental (Brunswick), October 18–20, 1951, led to an attempt to trace the increased radioactivity to atom bomb explosions in the United States and the corresponding measurements by Holter and Glasscock at Helena, Mont. For the explosions on October 6, 7, and 14 the probable track of air at the 500 mb level from Helena to Wittental was determined in each case and shown on a chart.

——— and Philipp, K. The path of an atomic explosion aerosol. Naturwissenschaften (Berlin), v. 40, 1953: 54 (in German).

Experiments at Wittental show that during October 16–24, 1951, a high value of the radioactive background was discovered. A similar high value had been reported at Helena, Mont., between October 6–16, 1951. It is suggested that the same air mass was at these two places at the different times and that radioactivity measurements permit the path of the air mass in which the explosion occurred to be plotted.

Sittkus, A. Observations on radioactive vapour from atomic experiments in the years 1953/54. Naturwissenschaften, (Berlin) v. 42, 1955: 478–482 (in German).

Records data from rainfall at Freiburg, Germany, on the radioactivity of the atmosphere and describes a method of deducing the time of the explosion from the observations.

———. The path of an atomic explosion aerosol. Remarks of Mr. Sittkus to W. Herbst. Naturwissenschaften, (Berlin) v. 40, 1953: 198.

No comparable effect was detected on other geiger counters in the same neighbourhood at the time when Herbst and Philipp recorded the effect they believe due to an atomic bomb. In reply these authors pointed out that they used thin-walled counters to detect β-radiation, whereas Sittkus used tubes suitable for detecting the penetrating component of cosmic rays.

———. Atomic energy and world weather. Universum natur and technick (Vienna) v. 16, 1954: 481.

———. Atomic energy experiments and weather. Osterreichische Hochschulzeitung (Vienna) 6 jg., Wien 1954 (in German).

Tsuzuki, M. Radioactive damage of Japanese fishermen caused by Bikini ashes. Münchener medizinische wochenschrift (Munich), v. 97, August 5, 1955: 988–994 (in German).

Short description of clinical experiences with radioactive injuries of the 23 fishermen during 1 year. All of the 23 fishermen in the boat were afflicted with acute radioactive-sickness as a result of contact with radioactive rain and ashes. They were injured through the combination of external as well as internal radiation.

INDIAN

Bandopadhyay, K. G., and others. Radioactive nuclei in rains over Calcutta. Science and culture (India), v. 21, 1955: 273–275.

The radioactivity in dusts carried down by rains between March and September 1955 were determined by β-ray assay. Histograms of relative activities as a function of specific rainfalls are given.

Chatterjee, Santimay, and others. Dating a nuclear explosion. Science and culture, v. 20, 1955: 403–404.

A method is proposed for dating nuclear explosions from the composite beta-decay curves of the radioactive dusts.

——— ———. Measurements on radioactive dusts over Calcutta. Science and culture, v. 20, 1955: 399–401.

A brief report of the measurements of the radioactivity of rain water samples collected in Calcutta from April 29 to the middle of July 1954, is presented. Measurements of energy and half lives indicated that the dusts originated from nuclear explosions.

——— ———. Presence of radioactive dusts over Calcutta. Science and culture, v. 19, May 1954: 570–571.

Beginning April 4, 1954, settled dust in Calcutta was analyzed for radioactivity; none was found until the first rain occurred on April 29.

ITALIAN

Neuwirth, R. Meteorological utilization of measurements of the artificial radioactivity of the air and precipitation. Geofisica pura e aplicata (Milan, Italy) v. 32, 1955: 147–158. (In German.)

German, French, and American measurements of the rainfall and air activity are being evaluated. For that purpose, trajectories from the experimental grounds for bomb tests in Nevada to Western Germany are drawn. By means of intermediate values, the test possibilities of air paths—first only scheduled—are given. The so-called deposit spaces and meridional circulations, which are significant particularly in divergence regions, prove to be of especial importance. The mechanism of activation of precipitation is discussed. A connection between the activity of precipitation and air masses could only be found in individual cases. But it seems that semitropical air air masses dispose of a higher specific activity in comparison with the polar air masses.

Radioactive precipitations caused by the experimental explosion of atomic weapons. Minerva medica (Turin) v. 46, March 31, 1955: 640–642 (in Italian).

Santomauro, L. and Cigna, A. First measurements of the radioactivity in atmospheric precipitations. Annali di geofisca (Rome), v. 6, 1953: 381–387.

Measurements conducted between February 1951 and November 1952 showed that nuclear-weapon tests at Las Vegas, Eniwetok, and Montebello were followed, 1, 2, and 3 weeks later, respectively, by an increase in the radioactive content of rain and snow falling in Italy.

Arizumi. On the distribution of ash-fall (meteorological investigation on the H-bomb experiment at Bikini Island—II) Journal of the Meteorological Society of Japan (Tokyo), Nos. 9–10, 1954.

Egawa, Tomoji, and others. Investigations on the contamination of field crops by artificial radioactivities as a result of the H-bomb tests at Bikini Atoll. Soil and plant food, v. 1, 1955: 19–20.

Crop samples taken between June and October 1954 were analyzed for radioactivity. Rare earth elements contributed the greater part of the activity. Polished rice showed no activity.

Horie, Kuniko. Damping of radioactivity of the Bikini ashes. Kagaku (Science) (Tokyo), v. 25, 1955: 636–637.

The radioactivity (β- and γ-radiation) of the H-bomb ashes was measured over a period of 600 days by means of an electroscope and a Geiger-Muller counter. Absorption by Al foils shows that the half-life is shorter for radiation of lower energy.

Ito, Gakuro and Moriuchi, Yasuyuki. Some problems on the radiological protection: especially concerning with the maximum permissible dose. Oyô Butsuri (Tokyo?), v. 24, January 1955: 3–17 (in Japanese).

Kakehi, H. Ash of Bikini and its effect on human body. Journal of Japan Physicians' Society, v. 31, May 1, 1954 (in Japanese).

Discusses physical and chemical composition of radioactive ashes which fell on the fishermen of the Fukuryu Maru and gives a clinical study of its effects. Estimated radiation received by fishermen in 2-week stay on ship as 200 r. Discusses hazard from contaminated tuna.

Kaneshige, Kankuro. Japan-United States radiobiological conference. Contemporary Japan (Tokyo), v. 23, Nos. 4–6, 1955: 296–310.

Kawabata, Toshihuri. Studies on the radiological contamination of fish. Japanese journal of medical science and biology (Tokyo), v. 8, October 1955: 337–372.

The decay rate of the radioactivity of the organs of fish caught by the crew of the "Shunkotsu Maru" was measured. After 3 months, the spleens, kidneys, and gonads retained considerable radioactivity, suggesting the presence of long-lived radioactive elements. At the end of this time, the liver and other organs retained only about 10 percent of the initial radioactivity and the bile had lost most of its activity. The retention by the pyloric caeca and the intestinal contents varied considerably and was probably dependent on the food consumed. Absorption of the ash of the organs on Dowex 50 and elution located most of the activity in the fractions eluted with 0.5 percent oxalic acid and 5 percent citrate buffers of pH 4.1 and 4.6. Qualitative separation with carriers identified the main radioactive element of the citrate buffer, pH 4.1, eluate as Zn^{65}.

Kimura, Kenjiro. Radioactive ashes on the fifth Fukuryu-Maru, the fishing boat that suffered from the hydrogen bomb test on March 1, 1954. Kagaku, (Tokyo) v. 24, 1954: 300–302.

By ordinary procedures with carriers and by separation with cation-exchange resins, the ashes were analyzed and the following radioactive nuclides were detected, Zr^{95} (65 days), Nb^{95} (35 days), I^{32} (2.4 hours), Te^{132} (77.7 hours), Nb^{95m} (90 hours), I^{131} (8.141 days), Ba^{140} (12.8 days), La^{140} (40.0 hours), Sr^{89} (53 days), Sb^{127} (93 hours), Ru^{103} (39.8 days), and Ru^{106} (1.0 year) etc.

———, and others. Detection of rhodium–103m in the "Bikini ashes." Bulletin of the Chemical Society of Japan, v. 29, 1956 (in English) 395–398.

The radiochemical analysis of the so-called Bikini ashes which fell on a Japanese fishing boat, the No. 5 Fukuryu Maru on March 1, 1954, are described as of some 25 days after detonation of the bomb. The collected sample (10^{-7} counts/minimum) was ignited and dissolved in 6N HC1, insolubles were filtered off, and the activity of small aliquots of the filtrate was measured. Total activity was estimated about 10^{-6} counts/minimum. Ru (10 mg.) was added to the filtrate as a carrier, the acidity of solution was adjusted to 2N, H_2S was passed through to precipitate R_u as sulfide, and the precipitate was dissolved with HNO_3; H_20, KM_n0_4, and concentrated H_2O_2. The appropriate aliquot portion of the distillate was taken up in a counting dish and evaporated to dryness; the activity was measured and found to be 1.5 x 10^{-5} counts/minimum.

Miyake, Y. Artificial radioactivity in rain water observed in Japan, from autumn 1954 to spring 1955. Papers in meteorology and geophysics, Meteorological Institute, Tokyo, v. 6, May 1955: 26–32.

At about midnight of September 18, 1954, a typhoon (No. 14, 1954) ran away toward the sea after attacking Japan. In place of the typhoon a colder and less moist air flowed in from the north. Just at the time, a new activity of artificial origin was detected in rain water at Niigata and Hirosaki, both situated along the Japan sea coast of the northern part of the main island. From 22d to 24th of September, the activity increased rapidly, spreading over a wide area in Japan and finally an activity as strong as 0.3 x 10^{6} curie/liter was counted in rain water at Yamagata.

———. The artificial radioactivity in rain water observed in Japan from May to August 1954. Papers in meteorology and geophysics, Meteorological Institute, Tokyo. v. 5, September 1954: 173–177 (in English).

Radioactivity in rainfall was measured at several places in Japan after the spring, 1954, Pacific tests. The maximum activity, 0.5 x 10^{-6} c/1, was observed at Kyoto on May 16, 1954. Meteorological trajectories indicate air that was over Bikini on May 8 reached Japan on the 16th and it is speculated that an explosion on May 5 is responsible for the activity. On August 3, airplane measurements with a dust impinger indicate 0.8 ~ 2.0 x curie/cc on the average from 1000–3000 meters over Tokyo.

Miyake, Y. Rain from south and snow from north. Kayaku Asahi, (Tokyo) December 1954 (in Japanese).

Discusses detection of nuclear explosions by various methods including observations of fission product activity in the atmosphere. Deposition of 750 cpm on a vaseline coated paper (30×30 cm) on May 13–16, 1954. Eighty-six thousand cpm/l observed in rain at Kyoto on May 14, apparently from May 5 test at Bikini. Thereafter, strong contamination of rain observed at many places on Pacific Coast of Japan. Since May 1954, activity of rain on Pacific side about an order of magnitude greater than on Japan Sea side of Japan. On September 22, 1954, a record-breaking 124,000 cpm/l from a Russian test was observed in rain at Yamagata, associated with a cold front advancing from Siberia, almost no activity in warm front rain on the Pacific coast. Discusses possible hazard from contaminated snow.

——— and Sugiura, Y. Radiochemical analysis of radio-nuclides in sea water collected near Bikini Atoll. Papers in meteorology and geophysics, Meteorological Institute, Tokyo, v. 6, 1955: 33–37.

A radiochemical analysis of sea water containing fission materials collected near Bikini Atoll in June 1954, was performed. The sea water was boiled with hydrochloric acid; iron and lanthanum salts each 5 mg as Fe and La were added to it. They were precipitated as hydroxide, which was dissolved in hydrochloric acid and ferric chloride was extracted with ethyl ether. The remaining solution was evaporated to dryness and the residue was dissolved in hydrochloric acid. Using the latter solution the group separation was done with cation exchanger resins.

———, and others. Artificial radioactivity in the sea near Japan. Papers in meteorology and geophysics, Meteorological Institute, Tokyo, v. 6, May 1955: 90–92.

Sea water collected around the Bikini Atoll from July to September 1954, was analyzed for total radioactivity by adding 2 g. solid NH_4Cl, 1 ml. of an aqueous solution of Ferric alum (86.3 g./l.), and 1 ml. of $BaCl_2$ solution (17.8 g./l.) to 1 l. of H_2O heated to 60–70 while being stirred. NH_4OH was added until the solution was faintly pink to phenolphthalein. After 2-minutes boiling the precipitate settled on standing for several hours at room temperature before being filtered on a filter disk lain above a glass filter. Counting rates of 2.1 ± 1.6 to 140.8 ± 6.8 counts/minute/l. were obtained.

——— ———. On the distribution of radioactivity in the sea around Bikini Atoll in June 1954. Papers in meteorology and geophysics, Meteorological Institute, Tokyo, v. 5, January 1955: 253–263.

Report of an oceanographic survey in the late spring of 1954 in the Marshall Islands area to investigate the radioactivity of the waters following the Castle tests. Maximum value was 7025 cpm/1, 450 km west of Bikini at a depth of 75 m (1,000 cpm $\approx$ 5.9 mμc). Almost all radioactivity was in solution, a filter of pore size 0.5μ passed 99 percent of the activity. Distribution of the radioactivity and its relation to ocean currents is shown. Vertical cross sections show marked decrease in activity below thermocline, about 150 m. Estimate flow of radioactivity through cross-section 150 km west of Bikini was 10^6 curie/hour. Coefficient in mixed fission product decay law ranged from −1.3 to −1.6, mean −1.5.

——— ———. Radiochemical analysis of fission products contained in the soil collected at Tokyo, May 1954. Papers in meteorology and geophysics, Meteorological Institute, Tokyo, v. 6, 1955: 93–94.

Soil (300 g.) was leached with 50 ml. 6N HCl on a steam bath and the filtered solution evaporated to dryness. The residue was dissolved in distilled water and an aliquot of the solution was subjected to chemical analyses, in which the sample was dried on a stainless steel planchet and its β-rays were counted. Group separation of the extract was made after addition of carriers of Ce, Ba, and Sr. Precipitation with H_2S showed very weak activity which was only a few percent of the total. The hydroxide group contained an appreciable amount of radionuclides, but most of them were insoluble when changed into fluoride forms. The filtrate of fluoride solution also showed a weak activity. The radionuclides obtained in the carbonate fraction were separated into Ca, Sr, and Ba and the Ca fraction was separated by concentrated HNO_3 and the Ba fraction obtained by precipitation as chromate. Results show radionuclides of rare earths $=9\times10^{-13}$ curie/g. $Sr^{89}=3\times10^{-13}$ curie/g., and $Ba^{140}=7\times10^{-13}$ curie/g.

Ohashi, S., and others. Pathological findings in the fatal case (the late Mr. Kuboyama) of the radiation sickness caused by Bikini ashes. An intermediate report. Iryo (Tokyo), v. 9, January 1955: 46–55 (in Japanese).

Autopsy findings and the case history are summarized from a case diagnosed as radiation sickness caused by exposure to fallout from a thermonuclear explosion. The patient died 207 days following exposure while on a fishing boat said to be located about 100 miles east of Bikini at the time of the explosion. Evidence was also found of a secondary virus hepatitis and aspergillus fumigatus pneumonia.

Otsuka, R. and Shimada, K. On the upper air current in lower latitude of the north western Pacific ocean at the beginning of March 1954. Meteorological investigation on the H-bomb experiments at Bikini Island. Journal of the Meteorological Society of Japan, v. 32, No. 7–8, 1954.

Ota, Michio, and others. Contamination of grapes by radioactive substances. Soil and plant food (Tokyo) v. 1, 1955: 43–44.

The K content of grapes was determined by measuring K^{40} content from 1951 to 1954. After the radioactive fallout in 1954, the grapes were shown to be contaminated by radioactivity.

Obo, Fujio. Radioactive rains and fishes in the Kagoshima area. Medicine and biology (Tokyo) v. 33, 1954: 19–23 (in Japanese).

Results are given of radioactivity determinations of rains, well and city water, vegetables, domestic animals, milk, and fishes. Radioactivity was determined in a radiation counter (Scientific Research Lab. model 32), at a distance of 1 cm. for 10 minutes. Samples were obtained during 18–27 May, 1954. The highest and lowest values obtained were: 4000–80 counts/min/1/ (c. p. m.) for rains, 20–0 c. p. m./cc. for well water, and 71–0 c. p. m./100 cc. for city water.

Radioactivity in the pelagic fish. Bulletin of the Japanese Society of Scientific Fisheries (Tokyo) v. 20, 1955: 907–926.

I. Distribution of radioactivity in various tissues of fish. Bulletin of the Japanese Society of Scientific Fisheries, v. 20, 1955: 907–915.

Pelagic fishes caught after atomic explosion experiment at Bikini Atoll in the Pacific were examined by radiochemical techniques. Generally the radioactivity was large in liver, kidney, gall bladder, and heart, and then in pyloric caeca, stomach, intestine, and gonad: there was little activity in skin, bone, and muscle. This order varied with species. Large radioactivity of the stomach contents did not necessarily mean large activity in the tissues, indicating considerable participation of diffusion of sea water into the fish body. Muscles from various sites showed slight difference in the activity. The dark muscle, however, showed several times as large activity as ordinary muscle.

II. Group separation of radioactive elements in fish tissues: p. 916–920.

Analytical group separation was performed with various ashed tissues of some fishes exposed to radioactive ash. The radioactivity was particularly large with element belonging to the third group, both A and B subgroups The second group showed considerable activity in pyloric caeca and kidney of skipjacks. The radioactivity of the first and fourth groups was detected in some tissues; the fifth group showed slight activity.

III. Separation and identification of zinc 65 in the muscle of skipjack.

Muscles of skipjack caught in the vicinity of the Bikini Atoll after the explosion were ashed, treated with Dowex 50, and eluted with various solvents. A fraction obtained with 0.5 percent oxalic acid and ammonium citrate (pH 4.18) contained Zn^{65}.

Saiki, Masamichi, and others. The radioactive material in the radiologically contaminated fishes caught in the Pacific Ocean in 1954. Bulletin of the Japanese Society of Scientific Fisheries (Tokyo) v. 20, 1955: 902–906.

The radioactivity of several samples of Coryphaena Hippurus caught in the southern Pacific in May 1954, after the atomic explosion at Bikini, was found, in decreasing order, in spleen, kidney, liver, pyloric caeca, heart, gill, intestine, gastric wall, ovary, testis, gastric content, red muscle, skin, vertebrae, and muscle. The red muscle of Neothunnus Macropterus showed 54.8 counts/min./0.20 g. activity on dry basis; the activity was decreased to 27.6 by soaking 25 g. muscle in 25 cc. water, and to 14.1 by soaking in 0.5 percent Na ethylenediaminetetraacetate solution. The radioactive substances in these fish tissues were found, upon analysis, to belong to the III group, particularly to III–B group. Examination of synchroscope patterns by scintillation counter indicated the presence of Zn^{65} among the radioactive substances. Sr^{90} was suggested to be present in very small amount.

Shimizu, Kentaro. Hiroshima and Bikini. Oriental economist, (Tokyo) v. 22, July 1954: 344–346.

A report by the doctor who treated the Japanese fisherman injured by the Bikini test.

Shinjiro, T. Death ash, experience of 23 Japanese fishermen. Japan quarterly, v. 2, 1955: 37.

Tajima, Eizo. Why fishing boats were contaminated by radiation. Shizen, December 1954 (in Japanese).

Many Japanese fishing boats were examined with a G–M counter following the Bikini tests of 1954. Decks and other washable parts were weakly irradiated, lamps and other unwashable parts were strongly irradiated. Directional relationships of contaminants on individual ships coincided with those of the prevailing winds. Ships to the west of Bikini averaged 123 cpm; those to the east, 1,800 cpm. Activity to the east shows sharp rises on test dates, sharp drops on other dates. To the west of Bikini, a strip of water from 15° N. to about the equator is contaminated, and the contamination of the boats may have been due to this.

Takase, Akira. Distribution of radioactivity in various tissues of fish and group separation of radioactive elements in them. Bulletin of the Institute of Public Health (Tokyo), v. 4, 1955: 27.

Radiological studies were made of several kinds of fish which had been caught in the fishing ground including the area from longitudes 128° East to 162° East and from latitudes 3° North to 33° North during the period from April 25 to July 7, 1954, and which had been rejected as highly contaminated radiologically at the time of landing.

———. Separation of the radioactive elements in the muscle of skipjack by ion-exchange resin, and confirmation of the presence of radioactive zinc. Bulletin of the Institute of Public Health (Tokyo), v. 4, 1955: 22–26.

An ashed sample of skipjack muscle caught in June 1954, near Bikini Atoll was analyzed for elements separated by an anion-exchange method (Dowex 50) with the use of 0.2N HCl, 0.5 percent oxalic acid, and 2 percent NH_4 citrate as eluents at each pH value of 3.53, 2.18, 4.60, 5.02, 5.64, and 6.42.

Yamada, Yoshio, and others. Measurement of radioactivity in contaminated crops. Soil and plant food (Tokyo), v. 1, 1956: 25–26.

A method called the direct method was developed to correct for natural K^{40} radiation in plant samples. The K_{20} content of the ashed sample is determined by flame-photometry. The radioactivity in a 100-mg. sample is measured and the natural radioactivity from K^{40} determined by calculation subtracted. Tea samples tested gave evidence of contamination by radioactive fallout.

Yamamoto, Ryozaburo. Atmospheric oscillation caused by the H-bomb. Astronomy and meteorology (Tokyo), v. 20 No. 8, 1954.

Yamasaki, F., and Koneko, H. On the artificial radioactivity in rainwater. Journal of the Scientific Research Institute (Tokyo), v. 49, June 1955: 137–143.

Rainwater in Tokyo was examined for artificial radioactivity from April to December 1954. The most active rain occurred on May 17, as reported by Miyake. Wide variability in activity was noted from sample to sample, even in the same rainfall. In a single rainfall, the specific activity appeared to be negatively correlated with rainfall intensity. Rainwater collected in the early stage of a single rainfall did not always show the strongest radioactivity. Exponent in the decay law for mixed fission products ranged from −0.9 to −1.4 in five rain samples investigated.

Yatazawa, Michihiko, and Ishihara, Takashi. Radioactive contamination of plants in Japan covered with fallout from H-bomb detonations in March–May 1954 at Bikini Atoll, Marshall Islands. I. Distribution of deposited radioactivity. Soil and plant food (Tokyo), v. 1, 1955: 21–22.

In May 1954 rains contained radioactivity up to 0.2 muc. per liter. The provisional permissible level of unknown radioisotopes in H_2O is given as 10^{-7} muc./ml. for β— or γ— emitters. The safety factor for these values is at least 100. From these values the permissible level for foods was calculated as 0.22 muc./day. Food plants tested ranged 0–1.25 muc./10 g. dry matter. It is concluded that serious radioactive contamination of plants was probable.

Warners, C. J. Note on radioactive compounds in the atmosphere. Tellus (Stockholm) v. 7, August 1955: 403–404.

Since January 1, 1955, daily measurements of the radioactivity of the air have been made by the Royal Netherlands Meteorological Institute. The highest values noted were in the period April 28–30, in tropical air transported from the south, and reached 27.4 x 10^{-10} μc per liter.

OTHER NATIONS

Akpinar, S. and Akpinar, R. Radioactive precipitations in Istanbul and Uludag (Turkey) Istanbul, v. 20C, 1955: 287–302 (in English).

From the decay curves of fission products in rain and snow, it was possible to determine the date of announced United States atomic tests and unannounced Russian tests with a probable maximum uncertainty of ± 8 days.

Gabites, J. F. Drift of radioactive dust from the British nuclear bomb test in October 1953. New Zealand Journal of science and technology (Wellington, N. Z.) v. 36B, September 1954: 160–165.

To account for the second wave of radioactivity which reached Wellington 38–54 hours after the blast in Woomera, Australia, it is apparently necessary to assume the material started from a height of 22,000–25,000 feet. The dust was dispersed downward by eddy diffusion and carried by lower level atmospheric circulations to New Zealand. The first wave which occurred 30 hours after the blast remains unexplained.

Rose, D. C. and Katzman, J. Radioactive deposits found at Ottawa after the atomic explosions of January and February 1951. Canadian journal of physics, v. 30, March 1952: 111–116.

Gamma-ray measurements indicated that considerable radioactive matter, apparently consisting of fission products, fell on January 29, and on February 7, 1951. The earlier fall came from an explosion in Nevada on January 27, and the February 7 material appeared to be 3 to 5 days old. The quantity was estimated to be equivalent to 1 γ Ra per square mile.

Ryder, N. V., and Watson-Munro, C. N. The detection of radioactive dust from the British nuclear bombs of October 1953. New Zealand journal of science and technology (Wellington, N. Z.), v. 36B, September 1954: 155–159.

Thirty hours after the nuclear explosion near Woomera, Australia, in October 1953, a peak in β-activity of 50 cpm was observed in Wellington, New Zealand, on an air filter. A second peak of 6 cpm was observed a few hours later. Decay curves indicated the activity was fission product activity.

Szalay, A. Unusual radioactivity observed in the atmospherical precipitation in Debrecen (Hungary) between April 22–December 31, 1952. Acta physica (Budapest, Hungary) v. 5, 1955: 1–14.

The authors investigated, by means of an end-window β-counter tube equipment the activity of precipitation fallen in Debrecen between April 22 and December 31, 1952. At times the precipitations showed radioactivity which proved to be due to fission products deriving from atomic explosions. These anomalous activities, with a lag of a few days, were in correlation to time with the atomic explosions published during the same period.

———. Radioactive fallout and radioactive strontium. Science, v. 123, April 20, 1956: 657–660.

Based on a speech given at Northwestern University, Evanston, Ill., January 19, 1956.

The radioactivity produced in magaton weapons is placed largely and immediately in the stratosphere while the smaller kiloton weapons produce clouds which do not reach into the stratosphere, and the bulk of their radioactivity is left in the troposphere. In the troposphere where rain occurs, particulate matter will be washed down in an period of days or weeks. It is easy to show that one-tenth inch of ordinary rainfall will probably remove almost completely all particulate matter except that which is so small as to be nearly of molecular dimensions.

Also in Ordnance, v. 41, July–August, 1956: 40–43, with title: Fallout from the A-bomb.

Reprinted in Congressional Record [daily edition] February 20, 1956: A1577–A1579.

Libby, Willard F. What the atom can do to you and for you. U. S. news and world report, v. 42, May 17, 1957: 64–75.
A member of the Atomic Energy Commission gives "authoritative" answers to such questions as: Should we worry over fallout from atomic tests? When will we get usable atomic power? Are new atomic weapons in sight?

———, and others. Forum on the Schweitzer declaration. Saturday review, v. 40, May 25, 1957: 8–13, 35–36.
There are four articles in this forum concerning atomic tests and the dangers of the resulting radiation. One is Dr. Libby's answer to the protest of Dr. Albert Schweitzer.

Lodge, Henry C. Data on atomic radiation. United States Department of State bulletin, v. 33, July 11, 1955: 54.

Lorentz, Pare. Fight for survival. McCalls, v. 84, January 1957: 28–29.
Dangers of radioactive poisons from bomb tests and radioactive waste.
Reprinted in Congressional Record [daily edition] January 28, 1957: A498–A500; February 7, 1957: A860–A862.

MacLeod, Iain. Nuclear explosions. Vital speeches, v. 21, April 15, 1955: 1165–1168.
House of Commons discussion on the effects of increased atmospheric radioactivity on mankind's hereditary constitution.

Mansfield, Michael J. From A-bomb to U-bomb. New leader, v. 38, May 23, 1955: 16–20.
Senator Mansfield, concerned about the dangers to life and health caused by atomic and hydrogen bomb tests, suggests the possibility of ceasing such experiments.

McWilliams, Carey. Perils unknown. Nation, v. 180, April 9, 1955: 302–306.
Severe indictment of the administration for its failure to report to the people on the dangers of atomic war, and for its failure to become concerned by the increased atmospheric radioactivity caused by repeated atomic tests.

Measured fallout; control of fallout. Time, v. 68, July 30, 1956: 61.

Miller, Harold. Nuclear weapons and genetics. Fellowship, v. 21, September 1955: 5–9.
Reprint of article originally written for British magazine Reconciliation by a medical physicist of Sheffield, England.

Miller, Robert W. Safeguarding children from radiation risks. Children, v. 3, November–December 1956: 203–207.

Muller, Hermann J. Race poisoning by radiation. Saturday review, v. 34, June 9, 1956, 9, ff.
Article on "local" and remote fallout and possible effects. Discussion of mutations produced by radiation.
Reprinted in Congressional Record [daily edition], v. 103, May 15, 1957: 6222–6225.

Next to last words. New republic, v. 136, May 6, 1957: 4.

New dangers of H-bomb. Science news letter, v. 67, March 5, 1955: 147.
Discussion of AEC's report on the Effects of High-Yield Nuclear Explosions.
Dreaded fission products come from A-bomb material which is present in only small amounts in H-bombs, if at all. Therefore, fallout problem probably less serious with H-bombs, except for their greater size.

Nishiwaki, Yasushi. Death in the rain. Nation, v. 180, August 6, 1955: 111–114.

Nordheim, L. W. Tests of nuclear weapons. Bulletin of the atomic scientists, v. 11, September 1955: 253–255, f.
Testing of atomic weapons is essential to their development. On the other hand such testing may prove dangerous because of radioactivity. The author examines the evidence on both sides and concludes that the dangers of the tests are much less than the dangers of being caught with inadequate weapons.

Now there's a warning about too much X-ray; scientists say it's far more dangerous than "Fallout." U. S. news and world report, v. 40, June 22, 1956: 60–70.
The National Academy of Sciences' report, June 13, 1956, contains estimate that the average person receives 30 times as much radiation from X-rays as from fallout.

Nuclear weapons tests; statements by scientists. Science, v. 124, November 9, 1956: 925–926.

The peril of strontium-90. Time, v. 69, May 6, 1957: 24.
Willard Libby's answer to Dr. Schweitzer on dangers of fallout.
Passin, Herbert. Japan and the H-bomb. Bulletin of the atomic scientists, v. 11, October 1955: 289–292.
This article tells how the accident in which several Japanese fishermen became victims of fallout has poisoned relations of Japan with the United States.
Poling, J. Men who really know about bomb-dust radiation! Better homes and gardens, v. 35, May 1957: 71f.
Radiation dangers. New republic, v. 136, May 20, 1957: 8–9.
"What is known about the hazards of bomb tests? What risks is it reasonable to run?"
Radiation hazards accumulate. F. A. S. newsletter, No. 57–4, April 15, 1957: 1 f.
Summary of recent news articles on nuclear testing and fallout.
Radioactive man. Economist (London) v. 180, July 21, 1956: 206.
Real power of the super-bomb; radioactive fallout. New republic, v. 131, November 8, 1954. 3–4.
Report on Hiroshima: Thousands of babies, no A-bomb effects. U. S. news and world report, v. 38, April 8, 1955: 46–48.
"From medical records of the only people who have lived through an atomic blast. Their children are normal. Radiation burns have healed. There's no radiation blindness."
Robinson, Donald. If H-bombs fall. Saturday evening post, v. 229, May 25, 1957: 25, 105–113.
"Exactly how would Americans behave under a thermonuclear attack? A special disaster-research team has come up with these surprising answers to an urgent question."
Rotblat, Joseph. The atomic challenge; radiological hazards. The new statesman and nation (London) v. 50, August 13, 1955: 177–178.
Discussion of (1) radioactivity, and its distribution resulting from fission; (2) radiation damage in a fallout area; (3) radiological hazards involved in peacetime uses of atomic energy.
Round the world tracer; tracing radioactive air masses. Time, v. 67, March 12, 1956: 73.
Rovere, R. H. Letter from Washington, perils of thermonuclear warfare. New Yorker, v. 31, February 26, 1955: 98–100.
Rs from the sky; fallout from test, March 1, 1954. Time, v. 65, June 20, 1955: 66.
Russell, Bertrand, Man's peril from the hydrogen bomb. The Listener (London) v. 52, 1954: 1135.
Safer H-bomb. U. S. news and world report, v. 41, July 27, 1956: 8.
Schweitzer, Albert. A declaration of conscience. Saturday review, v. 40, May 18, 1957: 17–20.
Complete text of Dr. Schweitzer's plea for control over the testing and military uses of atomic weapons. Stresses the radiation hazards involved.
Reprinted in Congressional Record [daily edition], v. 103, May 15, 1957: 6217–6221.
Sherrod, Robert. The grim facts of the H-bomb accident. Saturday evening post, v. 227, July 17, 1954: 20–21 ff.
"What really happened to those Japanese fishermen who wandered too close to the hydrogen blast at Bikini."
Stapleton, Bill. Navy vs. the H-bomb. Collier's, v. 134, July 23, 1954: 19–25.
"The heretofore secret story of 10 warships that were unexpectedly trapped in radioactive dust, but saved themselves with a shower of sea water."
Stevenson, Adlai E. Why I raised the H-bomb question. Look, v. 21, February 5, 1957: 23–25.
"The defeated Democratic candidate warns that H-bomb tests are still exposing all of us to a substance so lethal that just one spoonful would poison everyone on earth."
Straight, Michael. The ten-month silence. New republic, v. 132, March 7, 1955: 8–11.
Why did the administration wait 10 months after the H-bomb tests to tell the people of the lethal effects of fallout. Author criticizes AEC for its emphasis on secrecy.
Strauss, Lewis L. Truth about radioactive fallout. U. S. news and world report, v. 38, February 25, 1955: p. 35–38.
Strontium 90. (Editorial) Commonweal, v. 65, March 1, 1957: 556.

Teller, Edward. The nature of nuclear warfare. Air force, v. 40, January 1957: 43–47.
Main thesis: "If we so prepare ourselves that a terrible attack could hurt us but could not destroy us, then such an attack, I believe, will never come."
This dangerous planet. Newsweek, v. 45, January 17, 1955: 52–54.
This article is a consideration of the following question: "Is the lingering radiation spread around the earth by past or future H-bombs capable of generating [a] biological catastrophe, an insidious weakening of the human race, perhaps its extinction?"
Tunnel to nowhere. Atlantic, v. 199, April 1957: 6, f.
Article on radioactive waste disposal.
Unpleasant debate. Newsweek, v. 48, November 26, 1956: 64-66.
Describes debate among scientists on amounts of strontium 90 that can safely be absorbed by humans.
Same article, abbreviated with title, Will strontium 90 poison the world? Science Digest, v. 41, February 1957: 29–33.
Unseen cloud; Sir Anthony's Bikini. Economist (London), v. 179, June 16, 1956: 1077–1078.
Waddington, C. H. Atoms and genes. Nation, v. 183, August 18, 1956: 137–140.
Discussion of reports issued by National Academy of Sciences and British Medical Council on effects of radiation. Emphasizes dangers of fallout.
———. Peril from A-dust; with editorial comment. Nation, v. 180, February 19, 1955: 155–157.
War on the unborn. Economist (London), March 26, 1955: 1072.
Westergaard, M. Man's responsibility to his genetic heritage. Bulletin of the atomic scientists, v. 11, November 1955 : 318, f.
What the H-bomb fuss is all about. U. S. News and World Report, v. 41, October 26, 1956: 126–134.
Statements by Stevenson, Dewey, Dulles, Nixon, and Kefauver.
What will radioactivity do to our children? U. S. News and World Report, v. 38, May 13, 1955: 72–78.
Interview with Dr. H. J. Muller. Biggest danger is in the careless use of X-rays.
What you should know about danger from X-rays. U. S. News and World Report, v. 40, June 29, 1956: 44–48.
What's back of the "fallout" scare. U. S. News and World Report, v. 42, June 7, 1957: 25–28.
"Official position is that United States cannot afford to give Russia a monopoly on nuclear experiments.
Why is all the agitation directed against British and American bomb tests—and not against the tests conducted by Soviet Russia?"
White, E. B. Letter from the East. New Yorker, v. 32, November 3, 1956: 198–202 ff.
Wilson, E. Raymond. Japan's atomic fears. Christian century, v. 74, May 1, 1957: 553–554.
This article tells of Japan's efforts to be the "conscience of the world" regarding atomic and hydrogen bomb tests. The author feels that Japan's efforts toward leadership in abandoning such tests and in disarmament are not as effective as they might be.

Tiltman, Hessell. Japan feels intensely on H-tests. Washington Post, February 24, 1957: E3.

"Popular fears of radioactive contamination have passed the bounds of scientific evidence and become an emotional issue."

Two scientists back tests of H-bombs, New York Times, November 6, 1956: 45.

Dr. Edward Teller and Dr. Ernest Lawrence declared "The radioactivity produced by the testing program is insignificant."

U. N. gets three plans to curb atom tests. Washington Post, January 22, 1957: A11.

Three proposals laid before U. N. General Assembly's 80-nation Political Committee a few hours after AEC reported that the Russians had set off at least their fifth nuclear explosion since August.

1. Japan, Canada and Norway: Called for advance registration of all nuclear tests and for observation of the radiation results by U. N. experts.

2. Sweden: Proposed that all nuclear explosions be banned until the U. N. Scientific Committee on the Effects of Radiation had completed studies now in progress. This would amount to a 2-year moratorium.

3. Philippines: Proposed that Western powers and Russia agree on a common testing ground as the only place where nuclear explosions could take place. Tests would be registered and each country limited as to number and size of explosions permitted in any 1 year.

Ubell, Earl. Fallout danger seen only if H-war comes. New York Herald-Tribune, October 17, 1956: 1f.

———. Small X-ray dose kills human cell. New York Herald-Tribune, January 10, 1957: sec. II, p. 1.

Dr. Theodre Puck, biophysics professor of the University of Colorado, reported to a conference on cell biology that human cells could be killed with an X-ray dose of 96 roentgens. Previously scientists had believed human cells might withstand 300 to 200,000 roentgens. This new finding indicated that radiation from X-ray machines and atomic bomb fallout may be more dangerous than supposed.

Unna, Warren. Libby says test fallout won't be peril in any foreseeable circumstances. Washington Post, April 27, 1957: 1, f.

Young, Wayland. Ourselves and the bomb. Manchester Guardian, v. 76, March 28, 1957: 3.

Arguments against Britain's testing of an H-bomb at Christmas Island.

Warren, Shields. [Telegram to Lewis L. Strauss to correct Adlai Stevenson's statement of October 15, 1956, regarding dangers of strontium 90 from bomb testing] Washington, United States Atomic Energy Commission, October 17, 1956, 2 pp.

"Dr. Warren is scientific director of the Cancer Research Institute of New England Deaconess Hospital * * * one of the Nation's outstanding authorities on medical radiology, biology and pathology."

"From genetic standpoint, radioactive fallout including strontium 90 has given only small dose to date as compared with dose from naturally occurring and hence unavoidable background radiation. If weapons testing continues at present rate for 30 years, genetic dose still insignificant and only fraction of background."

Technical Reports

Agricultural and biological investigations pertaining to contamination by fission products (miscellaneous papers). Oak Ridge, Tenn., United States Atomic Energy Commission, Technical Information Service, 1954, 22 pp. (Foreign Weapons Effects Report 10).

Material received from the United Kingdom in connection with the Tripartite Conference in Washington, February 15 to 19, 1954, on the effects of Atomic Explosions on Human Beings and Their Environment, under area 2 of the Technical Cooperation Program. Complete transcripts of the proceedings of the 5-day conference are on file in the Classified Technical Library, AEC, and in the Armed Forces Special Weapons Project Headquarters, Washington, D. C.

Bell, Carlos G. Sanitary engineering aspects of long-range fallout from nuclear detonations. (Thesis) Oak Ridge, Tenn., United States Atomic Energy Commission, 1955, 248 pp. (NYO-4654).

Available from the Office of Technical Services, Department of Commerce.

Bradshaw, R. L. and Cottrell, W. D. Atomic weapons test fallout at ORNL on March 19, 1953. Oak Ridge, Tenn., Oak Ridge National Laboratory, 1953, 5 pp., photos.

Brookhaven National Laboratory, Upton, N. Y. A study of the airborne radioactivity at Brookhaven National Laboratory from the Nevada Tests, March through June 1953. Upton, N. Y., November 1953 (BNL 252 (T39)).

Routine and special observations were made at Brookhaven on the radioactivity in settled dust and rainwater during the Nevada tests in the spring of 1953, together with some meteorological interpretation. It was estimated that 30.2 curies of activity were deposited on the 25.9×10^6 square mile Brookhaven site during the 4-month period. Results of various monitoring devices are given. Rain samples were investigated for solubility of fission products. Using Whatman-41 filter (efficient down to 0.7μ) 27.5 percent of

activity in residue, 72.5 percent in filtrate. Using Whatman-41 and HA molecular filter (efficient down to 0.2μ) 83.4 percent of activity in residue, 16.6 percent in filtrate, indicating significant portion of activity on particles between 0.2 and 0.7 μ. Other studies on solubility of fallout and on variation in rainout during course of storm, also gamma energy spectrum of rainout.

——— ———. Summary and observations on radioactive fallout detected in the precipitation and dust during November and December 1952. January 16, 1953 (unpublished).

An increase in radioactivity was noted in routine Brookhaven surveys in the second week of November 1952. Radioautographs showed little evidence of specific centers of activity but showed slight clouding of the film after 4 days' exposure, indicating that most of the particulate activity was from very small particles. Total activity estimated to have fallen on the 25.9$\times 10^{10}$ cm^2 laboratory site during the 2-month period, November–December 1952, was:

	Curies
Settled dust, solid residue	.04
Settled dust, filtrate	.14
Precipitation, solid residue	.22
Precipitation, filtrate	.05
Total	.97

Setter, Lloyd R. and Goldin, A. S. Radioactive fallout studies in surface waters. Cincinnati, Ohio, United States Public Health Service, Robert A. Taft Sanitary Engineering Center, April 5, 1955.

Between March 10 and November 15, 1954, 79 rain and 6 dust samples were collected in Cincinnati, and measured for beta activity. A total of 0.53 μc per square meter was deposited during the period. The maximum accumulated activity at any one time was 0.125 $\mu c/M^2$ and by November 16 0.07 $\mu c/M$ remained from 1954 deposition, due to decay. An additional 0.0127 $\mu c/M^2$ theoretically remained from 1953 deposition. Vegetation, roofing, dust, etc., was 2 to 1,000 times more active than the rain. Nonfilterable activity in rain averaged from 46 to 69 percent of total, individual values ranged from 18 to 91 percent. Maximum rainfall activity 10.6 $\mu\mu c/ml$ on March 13. Studies of activity in cisterns and pond. Monthly average pond activity ranged from 28 to 230 $\mu\mu c/ml$, 57 to 92 percent nonfilterable.

——— ——— ———. Radioactive debris in North America from Operation TEAPOT, by Daniel Lynch. New York, August 1955, 6 pp. (NYO–4659).
Total fallout from the spring, 1955, Nevada tests as observed at over 100 stations in North America for the period of February 18 through May 20, 1955, is given. Fallout in the United States ranged from 3.1 millicuries per square mile at Ely, Nev., extrapolated to January 1, 1956. (Data in the immediate vicinity of the tests are not given.)
——— ——— ———. Radioactive fallout in North America from Operation TEAPOT, by R. J. List. Oak Ridge, Tenn., Technical Information Service, February 1956, 128 pp. (NYO–4696).
Meteorological trajectories of debris from the Nevada atomic tests in the spring of 1955 are given, together with the daily fallout at over 100 gummed-film stations in North America for the period February 18–May 20, 1955. Experiments indicate that on dry days, inverted and vertical gummed films collect about 40 percent as much as normal horizontal films; on days with precipitation, about 1 to 4 percent as much. Radio autographs of individual raindrops indicate that during a period of fallout at Chicago, about three drops in a hundred were radioactive.

Atomic energy in its repercussions on life and health. Paris, L'Expansion editeur, 1956, 254 pp. (in French).

Papers given at a scientific conference in Paris, July 1955, on dangers of atomic energy and radiation.

Garrigue, Hubert. Investigation of the atomic cloud. Publications scientifiques et techniques du Ministére de l'air. No. 228. [Paris] 1949, 24 pp.

In 3 out of 23 flights at 6,000 meters over France in July 1946, an unknown radioactive material with a half-life of 25 ± 5 hours was detected. Average concentration 0.013×10^{-16} curies/cm³ radio equivalent. The first detection was on July 20, 1946, 20 days after the first explosion at Bikini. Similar material was detected in 6 out of 15 flights in July, 1948, the first on July 2, 75 days after the Eniwetok test.

JAPANESE

Analysis of the "Bikini ash." (Special collection of papers). Tr. from Japan Analyst (Tokyo) v. 3, 1954: 333–368, 75 pp. (AEC–tr–2104).

Kimura, Kenjino. Introduction to special collection of papers: 1–6.

Incident of the Bikini ashes and the fishing boat is reported. Experiences on the boat are recorded, and fallout analyses are compared with those of Nagasaki and Hiroshima.

———. Radiochemical analysis of "Bikini ashes" fallen on board the No. 5 Fukurya Maru on March 1, 1954: pp. 7–27.

Comprehensive analysis was done in order to find the proper method of medical treatment for the victim fishermen on board. Analysis was started on March 18, and ash was found which consisted mostly of $Ca(OH)^2$, activity of which was 0.37 mc./g. on April 23. Cations of the third group (especially rare-earth metals) and fifth group were found to have strong activity by chemical separation. Fractions of each group, anions, Zr and Nb fraction, and U fraction were separated by an ion-exchange method.

Shiokawa, Takanobu, and others. Radiochemical studies on "Bikini ashes" (March 1, 1954): pp. 28–42.

Decay characteristics of the ashes which were brought back by the crew of the Fukuryu Maru No. 5 were; untreated ash $I = ct^{-1.81}$, water solution part $t^{-2.71}$ insol. part $t^{-1.68}$. Radioactive species separated by chemical method with carrier or collector were; nuclide, activity of nuclide (counts/min.) /activity of original sample (counts–min.), and the date of separation, Sr^{89} $6{,}000/80 \times 10^4$, April 24; Zr^{95}, $280/80 \times 10^4$, –; Ag^{111}, $200/200 \times 10^4$, April 14; Ru^{103}, $2.300/25 \times 10^4$ etc.

Yamatera, Hideo, and others. Radioactive dust from No. 5 Fukuryu Maru: pp. 43–54.

Analyses of radioactive dust collected on board No. 5 Fukuryu Maru were done by chemical separation and measurement of γ-ray energy and half-life of each species. Results are summarized as follows, radioactive nuclide and approximate percent of radioactivity given: Ru^{103}, 4.3–57; Ru^{106}, 1.4; Te^{129}, 1.3; I^{131}, 4.5; I^{132}, 1.0; Te^{132}, 1.0; etc.

Kiba, Toshiyasu and others. Radioactive substances found on the contaminated fish: pp. 55–60.

Radiochemical investigation was done on the substance collected from the surface of tuna fish which were brought back by the No. 5 Fukuryu Maru. Most of radioactivity was found on the scales, which could not be decontaminated by treating with H_2O; 80 percent of activity was removed by washing dried scales with 3N HCl. Paper chromatographic separation of the HCl fraction showed the presence of Ba^{140}, Sr^{89}, Te^{132}, and probably Zr^{95}, La^{140}, and rare earths.

Honda, M. A proposed method of analysis of radioactive substances in rainwater: pp. 73–75.

Kyoto, Japan, University. Institute for Chemical Research. The radioactive dust from nuclear explosion. November 1954, 133 pp. (Bulletin of the Institute for Chemical Research, Supplementary issue, November 1954) (in English).

Shimizu, S., and others. Radioactive dust from nuclear detonation. Survey of the radioactive contamination of the No. 5 Fukuryu Maru: pp. 1–3.

A collection of reports on investigations on No. 5 Fukuryu Maru, a fishing ship which was in the vicinity of the Bikini atoll when nuclear detonation occurred on March 1, 1954. The radiation dosage rate of contamination observed for combined β- and γ-radiation at every part of the ship on March 19, April 21, and May 16 is recorded. The av. value of total γ-dosage for the crew was supposed to lie between 200 and 500 r.

Kikuchi, Takehiko, and others. Properties and size of the radioactive ashes obtained from the No. 5 Fukuryu Maru: pp. 4–11.

Size and radioactivity of the ashes collected from the ship have been measured. Ashes consist of particles which appeared dark when observed through an occular microscope. When observed by side illumination the particles appeared white and several black spots were seen on the surfaces.

———. Radioautographic studies of the radioactive ashes obtained from the No. 5 Fukuryu Maru: pp. 12–17.

Radioautographic studies have been made of the radioactive ashes obtained from the ship by the use of X-ray film, radioautographic stripping plates, and plates of α-emitters. The radioactivity was found not proportional to the size of the particle, and the distribution of radioactivity in each particle was not uniform.

———. Radioautographic studies of the materials obtained from the No. 5 Fukuryu Maru contaminated by radioactive ashes: pp. 29–34.

The contamination was associated with the presence of small radioactive particles. Although these particles were easily scattered, it was difficult to remove them completely. The particles did not penetrate into the interior of clothes of fine meshes. Decontamination by washing with sea water was not perfect.

———. The contamination of the fishes caught by the No. 5 Fukuryu Maru and the foods manufactured from these fishes: p. 35–38.

The radio-contaminated tunas and other fish caught by the ship in the vicnity of Bikini Atoll were studied. The contamination was caused directly by radioactive ashes and was limited to the surface of the fish. No radioactivity was detected in muscles and bones. The contamination of tuna expressed as Co^{60} was 10^{-2}—10^{-3} microcurie per square centimeter of skin and 10^{-1} microcurie per g. scales.

Ishibashi, Masayoshi, and others. Radiochemical analysis of the Bikini ashes: pp. 35–39.

The following nuclides were detected in the Bikini ashes by radiochem. procedures: Ca^{45}, Sr^{89}, Y^{91}, Zr^{95}, Ru^{103}, Nb^{95}, Rh^{103m}, Ru^{106}, Te^{129}, I^{131}, Ba^{140}, La^{140}, Ce^{144}, Pr^{144}, and U^{237}. The ion-exchange method was used for analysis of contaminated rain water which fell on the Kyoto area on May 16, 1954 from which the presence of Sr^{89}, Zr^{95}, and Ba^{140}, was detected. Rare earths seemed also to be present.

———. Analysis of carrier-free radioisotopes by paper chromatography: pp. 60–74.

Rf values of Ru-Rh, Zr, Nb, Y, Ce-Pr, I, Ca, and Sr, are listed. Zr and Nb were separable only when they were developed with mandelic acid of pH 5.2 and 7.9 Elements of the Ce group seemed to be separated when developed with acetylacetone-BuOH.

Kikuchi, Takehiko, and others. The metabolism of fission products. I. The metabolism of the radioactive ashes obtained from the No. 5 Fukuryu Maru: pp. 75–83.

When the radioactive ashes were administered by mouth, the radioisotopes which were chiefly absorbed were alkaline earths, and were deposited mainly in the bones. When, after the removal of the alkaline earths, the radioisotopes contained in the radioactive ashes were administered by mouth in the form of chloride or citrate, the radioisotopes chiefly absorbed were heavy metals such as Ru and Rh.

———. I. Metabolism of the radioisotopes contained in the radioactive ashes obtained from the No. 5 Fukuryu Maru: pp. 84–90.

Among the radioisotopes obtained by separation from ashes on the ship, i. e., Y^{91}, $C^{141, 144}$, Pr^{144}, Ca^{45}, $Sr^{89, 90}$, $Ru^{103, 106}$, Rh^{106}, Zr^{95}, Nb^{95}, and I^{131}, Sr, Ca, and Y were accumulated chiefly in the bones of adult mice, and the elimination of radio-Sr from there was very slow. When administered by mouth, radio-Sr and Radio-Ca were readily absorbed from the digestive tract, while the absorption of radio-Y from the tract was poor.

———. Paper XI, Studies on the metabolism of fission products III. Radioautographic studies on the localization of radiostrontium and radiocalcium in the bones: pp. 99–105.

———. The effects of EDTA–Na (Na Ethylenediaminetetraacetate) upon the metabolism of radiostrontium and radioyttrium in mice: pp. 106–111.

The toxicity of EDTA–Na, inert Sr $(NO_3)_2$ and Ba $(NO_3)_2$ has been examined. Simultaneous injection of EDTA–Na showed no significant effect upon the distribution of radio-Sr in the bones of mice. The distribution of Radio-Y in the bones of mice tended to decrease following the simultaneous subcutaneous injection of Y^{91} and EDTA-Na.

Japanese Committee for Compilation of Report on Research in the Effects of Radioactivity. Research in the effects and influences of the nuclear bomb test explosions. Tokyo, Japan Society for the Promotion of Science, 1956: 1824 pp. in 2 v.

Hearing before the Joint Committee on Atomic Energy, 84th Congress, 1st session, April 15, 1955. Washington, United States Government Printing Office, 1955, 60 pp. (committee print).

Testimony by various authorities, including AEC and Weather Bureau experts, on various phases of possible hazards from atomic tests. Eisenbud states the cumulative fallout in the United States from early 1951 to January 1, 1955, varies from 21 millicuries per square mile in Arizona to 120 millicuries per square mile in New Mexico. The normal radioactive background in the United States varies from about 0.01 to 0.05 mr/hr. On six occasions, the background radiation was elevated to about 1 mr/hr beyond a few hundred miles from the test site, Troy, Chicago, Rochester, Salt Lake City (twice) and one other.

APPENDIX 10

OAK RIDGE NATIONAL LABORATORY,
Oak Ridge, Tenn., August 21, 1957.

Mr. JAMES T. RAMEY,
Executive Director, Joint Committee on Atomic Energy,
Washington, D. C.

DEAR MR. RAMEY: Enclosed please find a copy of the material concerning topic VIII D of the outline, fallout and water decontamination, requested by Congressman Holifield for the Joint Committee on Atomic Energy Report.

Enclosed is the biographical sketch also requested in your letter of June 19, 1957.

If I can be of any further assistance to you and the committee, please feel free to write.

Thank you.

Very truly yours,

WILLIAM J. LACY,
ERDL Representative at ORNL.

Enclosures: 1. Report on Fallout. 2. Biographical sketch.

Cc: Commanding Officer, Engineer Research and Development Labs, Fort Belvoir, Virginia; Harry N. Lowe, Jr., Chief Sanitary Engineering Branch, Fort Belvoir, Virginia; Dr. Karl Z. Morgan, Director, Health Physics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee.

BIOGRAPHICAL SKETCH

William J. Lacy was born in 1928 in Wallingford, Connecticut, attended Lyman Hall High School where he won the prizes in science and chemistry, then he obtained a B. S. degree in 1950 from the University of Connecticut where he majored in Chemistry. He entered graduate school at New York University in September of 1950 and worked as a research associate on an AEC research contract. In May of 1951 he joined the staff at the Engineer Research and Development Labs of Fort Belvoir, Virginia, and immediately was transferred to the Oak Ridge National Laboratory to work on the water decontamination research project.

He has had seven (7) articles published, presented numerous papers and is a member of the American Chemical Society, American Association for the Advancement of Science and the Scientific Research Society of America.

Mr. Lacy is married and has two (2) sons, 2½ and six months, he resides in Oak Ridge, Tennessee.

[Material for Joint Committee on Atomic Energy Topic VIII D]

REMOVAL OF RADIOACTIVE FALLOUT FROM CONTAMINATED WATER SUPPLIES

William J. Lacy, Chemist,* Sanitary Engineering Branch, Engineer Research and Development Labs, Fort Belvoir, Va.

There are two possible sources of radioactive contamination of public water supplies, (1) the result of direct discharge into the environment from reactor processing plants, research center using radioisotopes and others and (2) deposition of radioactive material by fallout or wash-in due to weapon's test activities.

Most of the radioactive materials in item one are in solution, fallout, however, may be in the form of insoluble oxides, and its removal may differ from the removal of ionic material.

Studies have been reported on the subject of fallout in particular areas (1), (2), (3), (4). It was reported that 35 percent of the fallout activity was removed by the Albany, New York, water treatment plant, an alum coagulation, settling and filtration plant. Thomas and his coworkers at Harvard (2) (3) working at the Lawrence, Massachusetts, water plant obtained 80 percent removal by coagulation, settling, and filtration. Bell (4) compared the fallout removal results from Cambridge and Lawrence, Massachusetts, and Rochester, New York, with pilot plant results obtained by Straub (5) (6) who used a simulated bomb blast mixture with an age about one month after detonation.

*On loan to Health Physics Division, Oak Ridge National Lab., Oak Ridge, Tennessee.

The comparison indicated the three treatment plants show much lower removals of fallout than Straub obtained on chemical processed radioactive material even though the same procedure was used in both cases. The U. S. P. H. S. reported the analysis of rain water samples containing fallout showed 50 to 100 percent of the "old" radioactive material to be soluble. However, the soluble fraction dropped to about 30 percent during the weapon's testing period.

For reactor made fission products, or a mixture of commercially available radioisotopes, the efficiency of removal would be a function of the various radioelements comprising the mixture. Results in laboratory studies and pilot plant scale investigations by the author indicates removals of about 70 to 85 percent using either alum and soda ash or ferric chloride and limestone coagulants. A series of studies (7) reported that removals of 99 percent could be obtained using a serial coagualtion procedure including an excess lime-soda ash softening or phosphate coagulation step, provided some clay material was added to remove radiocesium.

Conventional wastes treatment processes include coagulation, settling, and filtration, plus disinfection. Often additional treatment, such as fluoridation, aeration, softening, ion exchange, iron and manganese removal are employed.

During coagulation certain of the dissolved constituents are precipitated as insoluble hydroxides or carried along, scavenged, with the heavy metal hydroxides of alum or iron. Coagulation can have its radioactivity removal increased from about 75 percent to almost 90 percent by the addition of clay for cesium and copper sulfate for radioiodine.

It should be pointed out that different radioisotopes respond differently to removal by coagulation. Other factors to be considered include: (1) Chemical and physical form of the radionuclide, (2) concentration or the radioactive material, and (3) optimum pH of flocculation for the coagulant available and the water under treatment. Investigation by the author (8) indicates increase dosages of chemical generally yielded only slightly higher removals while higher pH usually resulted in proportionately higher removals.

Softening using lime-soda ash is one of the more effective chemical methods for the removal of radiostrontium and barium. However, it is necessary to use excesses quantities, over the stoichiometric dosage, for satisfactory results. Studies at MIT (9) (10) have indicated that the radiostrontium is removed by coprecipitation with the hardness or calcium carbonate in a mixed crystal formation.

Ion exchange is another method used by some municipal water treatment plants. Removal of ionic radionuclides by this process is not only technically possible (11), but very satisfactory. The most effective method employes either a mixed bed principal or separate cation-anion exchange columns. Ion exchange units such as home-type water softeners are very effective for removal of 99+ percent of the radioactive fallout or reactor originated radionuclides from contaminated water. Also ion exchange resins (mixed) can be used with, good results, as slurries for the removal of a vaniety of radioactive contaminants from water solutions (12)

Other methods, such as, the use of clays, powdered metal, charcoal, flotation and various adsorbents all have some merit for the removal of specific radioisotopes or under a given set of condition result in good removals. (13) However, clay seems to have the most practical and over advantage of being (1) available, (2) cheap, (3) effective, (4) simple to use, (5) easy to remove both absorbent and absorber and the radioactive material will not be easily leached once it is attached to the clay particle. Distillation although not a usual municipal water treatment method is used extensively by the military on island bases and where a high quality of water is required. Distillation results in the best single treatment of a contaminated water removing 99.9+ percent. (14) The major objection to distillation as a water treatment procedure is cost.

As indicated by the literature cited most of the above studies have been made on chemically processed, radiochemically pure radioisotopes and not true fallout from a nuclear detonation. Therefore, it was expected that the actual fallout material not being entirely in the same physical and chemical form could not be as readily removed from contaminated water. However, recent tests by the Corps of Engineers at the AEC Nevada Proving Grounds on some very low level fallout indicated (1) close agreement with laboratory results on removal by coagulation and softening using lime-soda ash and precipitation with trisodium phosphate at a high pH, (2) the ion exchange procedures resulted in 99 to 100 percent removal of the bomb fallout material, (3) the material that was not

a true solution could be removed physically and the material in solution treated chemically and (4) radionuclide once adsorbed on clays were not appreciably leached by tap water.

Many other experiments have been made by myself and others, some are still in progress, which have not been cited here. It is felt that this brief general review plus the six tables showing detailed data, will give the committee a review of the field on water decontamination.

*Glass wool reflux condenser used.

NOTES

MFP-1 was 3-year-old fission product mixture.
MFP-2 was a 2-week-old mixture from disolution of a reactor slug.
MFP-3 was composite sample or ORNL liquid waste.
MFP-4 concentrate from ORNL liquid waste evaporator.
MFP-5 mixture to simulate the material expected 10 days after atomic detonation.

APPENDIX 11

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington 25, D. C., August 20, 1957.

Hon. CHET HOLIFIELD,
Chairman, Special Subcommittee on Radiation of the Joint Committee on Atomic Energy, House of Representatives, Congress of the United States.

DEAR MR. HOLIFIELD: At the suggestion of your Committee, the Division of Biology and Medicine, U. S. Atomic Energy Commission, invited the principal participants in the discussions involving predictions of future skeletal concentrations of strontium 90 in humans which took place at the recent Congressional Hearings on fallout to meet once again in an attempt, insofar as present information permitted, to reduce the degrees of uncertainty in these predictions.

This meeting took place on July 29, 1957 and I am pleased to transmit a summary report of the meeting based on the stenographic transcript and consultation with the principal participants. This report was prepared by Dr. Forrest Western, of the Division of Biology and Medicine. It is my opinion this report honestly and clearly reflects the views of the participant scientists with respect to this problem. This document, then, would appear to reflect the thinking of those scientists who have worked hardest and thought most on the subject of these predictions, and should, therefore, be a useful addition to the text of the very important and

informative Hearings which your Committee held in May and June of this year on the whole matter of fallout from weapons tests.

Sincerely yours,

CHARLES L. DUNHAM, M. D.,
Director, Division of Biology and Medicine.

PREDICTED SKELETAL CONCENTRATIONS OF STRONTIUM 90

INFORMAL DISCUSSION OF JULY 29, 1957

At the suggestion of the Joint Committee on Atomic Energy, the Division of Biology and Medicine, U. S. Atomic Energy Commission, invited the principal participants in discussion of this subject at the recent Congressional Hearings, May 27–June 6, 1957, to meet in Washington, D. C., July 29, to try to reduce the degrees of uncertainty involved in various predictions of future skeletal concentrations of strontium 90 in humans. These persons were: Mr. Merril Eisenbud, Dr. J. Laurence Kulp, Dr. Wright H. Langham, Dr. Willard F. Libby, Dr. Lester Machta, Dr. William F. Neuman and Dr. Walter Selove. In addition to these participants were: Dr. Charles L. Dunham who alternated with Dr. Libby as Chairman of the discussion, Dr. Lyle T. Alexander, Mr. Hal Hollister, Dr. J. Calvin Potts, Dr. Robert Reitemeier, and the author of this summary, Forrest Western. This summary is based on a stenographic transcript and has had the benefit of comments by most of the participants.

It was generally agreed that the extensive measurements by Dr. Kulp of concentrations of strontium 90 in human skeletons established one base from which one may extrapolate skeletal concentrations of strontium 90 to be expected in the future. Dr. Kulp stated that the average concentration in children of the northeastern United States in the fall of 1956 was about 0.8 micromicrocuries of strontium 90 per gram of calcium. In discussion of relationships between concentrations in the United States and other parts of the world, Dr. Kulp indicated that concentrations in children of northeastern United States are consistent with those of two widely separated areas in other parts of the world from which he has been able to obtain a considerable number of samples. Dr. Selove discussed reports of relatively high local concentrations of fallout in an Asiatic area and suggested that possible fluctuations in local patterns of tropospheric fallout in the periods shortly following tests explosions might result in considerably higher skeleton concentrations in some areas of the world. Although our world sampling program to date has failed to disclose areas in which skeletal concentrations are higher than in the United States, individual comments endorsed the desirability of continued search for such areas as a part of our world-wide study of the distribution and uptake of fallout from nuclear detonations.

It was agreed that, *even if fallout had ceased at the end of 1956*, skeletal concentrations of strontium 90 would be expected to increase until they came into equilibrium with the strontium 90 in the environment. Somewhat independent estimates of the equilibrium value may be made (1) from a knowledge of *changes* in environmental (specifically, *dietary*) concentrations during the growth of the skeletons assayed, and (2) by application of factors of discrimination between calcium and strontium in estimating the uptake of strontium 90 from existing concntrations of strontium 90 (a) the soil, (b) the over-all diet, or (c) milk. Each of these methods involves some degree of uncertainty. After discussion of the uncertainties involved, it was agreed that these various considerations make it appear probable that average skeletal concentrations to be expected in young persons of northeastern United States as a result of strontium 90 actually deposited on the earth's surface up to the end of 1956, fall between 1.5 and 2 micromicrocuries per gram of calcium.

Because some of the strontium 90 released to the stratosphere in past years has not yet been deposited on the earth's surface, actual skeletal concentrations from tests performed before the end of 1956 may be expected to become greater than the values estimated under the conditions assumed above. The increase in concentration to be expected from additional fallout of this material depends upon a number of factors; (1) the additional activity reaching the surface of the earth, (2) the fact of delay in the appearance of additional strontium in the diet, (3) the relative importance of total soil content and rate of fallout (specifically, rate of retention on surfaces of vegetation), (4) radioactive decay and (5) decrease, with time after fallout, in the percentage of strontium 90 in the soil which is available for uptake by plants. It appeared from the discussion that the greatest uncertainty involved here is in predicting the distribution and time of fallout to be expected from residual stratospheric content.

It was estimated that, in addition to the range of uncertainty by a factor of 1.25 represented in the above estimate of the average skeletal concentrations to be expected from strontium 90 actually deposited on the earth's surface by the fall of 1956, there might be an additional range of uncertainty, by a factor as large as two, in estimates involving the ratio of the quantity of strontium 90 in the stratosphere to that on the ground. In estimating total skeletal concentrations in the northeastern United States which might be expected when fallout of strontium 90 produced prior to 1957 is essentially complete, these two uncertainties alone would result in a range of a factor of 2.5 between minimum and maximum estimates.

It was agreed that the first effort of the group would be to estimate average skeletal concentrations to be expected in the age group of maximum concentration in 1975, assuming that there were no nuclear detonations after 1956. Dr. Kulp estimated that, because of radioactive decay and decrease in availability, additional fallout of strontium 90 produced before 1957 would not make environmental concentrations of strontium 90 in the northeastern United States in 1957 significantly greater than in 1956. After discussion, this led to the estimate that, if the residual stratospheric content were to be deposited with uniform distribution over the surface of the earth, skeletal concentrations in the age group of maximum concentration in 1975 would fall in the range of from 1.5 to 3.5 micromicrocuries of strontium 90 per gram of calcium.

Mr. Eisenbud, taking a different approach, first estimated quantities of strontium 90 on the surface in the northeastern United States at the end of 1956 due to tropospheric and stratospheric fallout, respectively, and the fraction of strontium 90 previously injected into the stratosphere which had fallen out by the end of 1956. Maximum future environmental levels were then related to those of 1956, using the assumption that fallout of the residual (1956) stratospheric content would have the same geographic distribution as the previous stratospheric fallout. Discussion of this approach led to an estimate of skeletal concentrations, in 1975, in the range from 2 to 5 micromicrocuries of strontium 90 per gram of calcium.

Dr. Machta discussed the possibility that strontium 90 injected into the stratosphere near the equator may be moving northward and entering the troposphere preferentially above 30° N., in such a manner that the fraction of the stratospheric content falling out in these latitudes is increasing with time. It was estimated that such "banding" of fallout might result in skeletal concentrations two times as high as those estimated on the basis of Mr. Eisenbud's assumption of a constant stratospheric fallout pattern; i. e., an average skeletal concentration in children of from 4 to 10 micromicrocuries per gram of calcium.

It was agreed that at this time our knowledge of atmospheric transport is too limited to reduce the range of uncertainty on this point represented by the ranges of estimated concentrations described in the preceding three paragraphs.

It was estimated that, if testing of weapons were continued up to about 1965 in such a manner as to produce strontium 90 in the same total quantity and with the same distribution (i. e., with tests held at the same geographical locations and with the same distributions of tropospheric and stratospheric fallout) as were produced prior to 1957, the average total skeletal content in young persons in about 1975 might be approximately 2.5 times that to be expected if there were no further testing. This factor is considered to apply equally to the three estimates discussed in the preceding paragraphs.

The estimates described above are summarized in the following table:

Predicted average skeletal levels of strontium to be expected in young persons in northeastern United States under various conditions of testing of nuclear weapons

[All levels are in micromicrocuries of strontium 90 per gram of calcium]

Concentrations in children, fall 1956	Predicted future concentrations from strontium 90 on ground before 1957	Predicted concentrations in 1975 from all strontium 90 produced before 1957	Predicted concentrations in 1975 if past tests or equivalent were repeated before 1965
0.8	1.5 to 2	1.5 to 3.5*	3.5 to 9.*
		2 to 5	5 to 12.
		4 to 10	10 to 25.

*The considerations leading to each of these 3 estimates are discussed in the text of this summary.

It was the consensus of the group that within one or two years the confidence with which predictions of future concentrations can be made will be so greatly increased that it is unprofitable for the present purpose to extend predictions beyond those given in the above table.

APPENDIX 12

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington 25, D. C., June 1, 1957.

Hon. CHET HOLIFIELD,
Chairman, Special Subcommittee on Radiation, Joint Committee on Atomic Energy, Congress of the United States.

DEAR MR. HOLIFIELD: Your letter of 31 May 1957 requests a letter on an unclassified basis giving: (a) an estimate as to year-to-year fission yield and total yield put into the atmosphere by atomic weapons from all sources; (b) a list of weapons test series conducted by each country; and (c) a listing of the number of explosions which have taken place, country by country and year by year.

As to total yield and total fission yield released by tests to date either in gross or by nation, this information has security implications which preclude my giving it as unclassified data. Various unclassified estimates which do not reveal such totals have been made as to the amount of fission debris making its way into the stratosphere. One such estimate is that given on pages 952 and 954 of the attached report, "Current Research Findings on Radioactive Fallout," by Dr. Willard F. Libby.

Information as to U. S. test series and the number of shots in each is contained in the following table:

Name of series	Date	Number of shots
Trinity	1945	1
Crossroads	1946	2
Sandstone	1948	3
Greenhouse	1951	4
Ranger	1951	5
Buster/Jangle	1951	7
Tumbler/Snapper	1952	8
Ivy	1952	2
Upshot/Knothole	1953	11
Castle	1954	(1)
Teapot	1955	14
Wigwam	1955	1
Redwing	1956	(1)
Plumbbob	1957	[2] 1

[1] The number of shots in Castle and Redwing is still classified.
[2] Only 1 shot to date.

The above list is exclusive of the two weapons detonated in combat during World War II.

With respect to the British series, the United Kingdom has announced the following series and number of shots:

Location	Date	Number of shots
Australia	1952	1
Do	1953	2
Do	1956	2
Do	1956	4
Christmas Island	1957	2

Of several Soviet references to their tests, they have: announced one on 20 August 1953, shortly before the U. S. announcement was issued; made a general statement on 18 September 1953 to the effect that they had conducted several tests in recent weeks which constituted confirmation of the U. S. announcement of 31 August 1953; and announced a test on 10 September 1956 about which the U. S.

made no comment. The United States has from time to time announced certain of the tests. Copies of these announcements are attached. From a review of these announcements it can be noted that the U. S. has announced 23 specific USSR detonations. A complete list of all detected shots cannot be provided on an unclassified basis. In this respect on August 26, 1956, the Chairman of the AEC stated: "Although there have been but 13 announcements by the U. S. regarding Soviet testing, several have noted a series of detonations and the actual number of Soviet detonations is significently higher than 13."

Should you desire a classified summarization of the information requested which cannot be given on an unclassified basis, I would be most pleased to provide this separately.

Sincerely yours,

K. E. FIELDS,
General Manager.

[From Congressional Record, June 18, 1957]

NUCLEAR WEAPONS EXPLOSIONS

The following table has been compiled principally from press releases of the United States Atomic Energy Commission. However, reports in the press as to the size and nature of various explosions have been included when available.

On April 12, the United States had announced 19 Soviet tests. The AEC has pointed out that this country does not disclose all of the U. S. S. R. shots of which it has knowledge but limits itself to statements about explosions of special interest. The actual number of Soviet detonations is therefore significantly higher than those announced.

As of June 17 the AEC had announced 68 tests by the United States. However, the total number of detonations made by this country has never been announced.

The United Kingdom has announced 11 tests to date, June 18, which is understood to be the total number of tests made by that country.

Year	United States		U. S. S. R.		United Kingdom		Remarks
	Date	Place	Date	Place	Date	Place	
1945	July 16	Alamogordo					1st test of A-bomb.
	Aug. 6	Hiroshima					Air burst, energy release about 20,000 tons of TNT.
	Aug. 9	Nagasaki					Do.
1946	July 1	Operation Crossroads, Bikini Lagoon.					Air burst, Nagasaki-type bomb.
	July 25						Underwater detonation.
1948 (spring)		Operation Sandstone, Eniwetok Atoll.					3 explosions announced May 17, no details given.
1949			Sept. 23	Soviet territory			1st atomic explosion in U. S. S. R. announced by President Truman.
1951 (winter)	Jan. 27 Jan. 28 Feb 1 Feb. 2 Feb. 6	Operation Ranger, Nevada Flats.					5 tests primarily for tactical information, Air bursts.
1951	April and May	Operation Greenhouse, Eniwetok.					4 tests described as "experiments contributing to thermonuclear research."
			Oct. 3	Soviet territory			2d explosion. Reported by the United States, later confirmed by the Kremlin.
			Oct. 22	do			President Truman announced evidence of a 3d nuclear explosion by the U. S. S. R.
1951	Oct. 22 Oct. 28 Oct. 30 Nov. 1 Nov. 5 Nov. 19 Nov. 29	Operation Buster Jangle, Nevada Flats.					7 air, tower, and surface or underground bursts. Low yield. Tactical.
1952	Spring and summer Apr. 1 Apr. 15 Apr. 22 May 1 May May 25 June 1 June 5	Operation Tumbler Snapper, Nevada Flats.					8 air and tower bursts. Troop participation in some tests.
	Fall	Operation Ivy, Eniwetok					2 tests. 1 was the 1st hydrogen bomb ever exploded. Yield 5 megatons.
					Oct. 3	Monte Bello Islands.	Nature of bomb not disclosed. Probably of Hiroshima type.

Year	United States		U. S. S. R.		United Kingdom		Remarks
	Date	Place	Date	Place	Date	Place	
1953	Mar. 17 Mar. 24 Mar. 31 Apr. 6 Apr. 11 Apr. 16 Apr. 25 May 8 May 19 May 29 June 4	Operation Upshot Knothole, Nevada Flats.					11 tests: Air, tower, and 1 shot from a 280-millimeter gun. The largest explosion, that of Apr. 18, was reportedly equal to 30,000 to 40,000 tons of TNT.
			Aug. 12	Soviet territory			Initial hydrogen bomb (nondeliverable).
			Aug. 31	do			Fission explosion in same range of energy release as Nevada Flats tests.
1954	Mar. 1	Operation Castle, Bikini					Hydrogen bomb reported to have had a yield of 15 megatons. Radioactive fallout over 7,000 square miles.
	Mar. 26						No information released concerning this test.
	Apr. 6	Eniwetok					3d test in the series. Presumably an H-bomb.
			Oct. 26	Soviet territory			Announcement made by the AEC of a series beginning in September.
1955	Feb. 18 Feb. 22 Mar. 1 Mar. 7 Mar. 12 Mar. 22 Mar. 23 Mar. 29 (2 tests) Apr. 6 Apr. 9 Apr. 15 May 5 May 15	Operation Teapot, Nevada Flats.					14 air, tower, and underground tests. Included atomic trigger for detonating H-bombs, also civil defense test and "air-killer" test.
	May 17	Operation Wigwam, off west coast.					Small underwater atomic weapon exploded, probable yield 1,000 to 5,000 tons of TNT.
			Aug. 4	Soviet territory			AEC announced that the Soviets had resumed testing of nuclear weapons.
			Sept. 24	do			Announcement by AEC of another Soviet nuclear explosion.
					Oct. 15	Woomera Rocket Range, Australia.	2 tests, the 1st equivalent to 20,000 tons of TNT. No data for the 2d test.
			Nov. 10	Soviet territory			Announcement by AEC of a further test in the 1955 series.

			Nov. 23	do			Hydrogen bomb in the range of megatons. Khrushchev announced on Nov. 27 that it was a hydrogen bomb and that it had been dropped at a great height from an airplane.
1956			Mar. 21	Soviet territory, probably central Asia.			AEC announced another Soviet nuclear explosion.
			Apr. 2				Another explosion in current series announced by AEC.
	May 5	Operation Red Wing, Eniwetok.					Relatively small device exploded, about 10 kilotons.
					May 16	Monte Bello Islands.	Test expected to supply data for triggering of H-bomb.
	May 21	Bikini					1st H-bomb dropped by U. S. Air Force. Yield at least 15 megatons.
			Aug. 24	Southwestern Siberia.			
			Aug. 30				A series of small explosions.
			Sept. 2				
					Sept. 27	Maralinga Proving Ground, South Australia.	4 tests, tower and air; new and cheaper kinds of A-bombs tested.
			Nov. 17	Southwestern Siberia.			Small explosion.
			Jan. 19	do			
			Mar. 8				
			Apr. 3				
			Apr. 6				Moscow announced these tests were designed to perfect atomic warheads for tactical purposes.
			Apr. 10				
			Apr. 12				
			Apr. 16				
					May 15	Christmas Islands.	H-bomb dropped from Vikers Valiant jet bomber. Energy release 1,000,000 tons of TNT.
	May 28	Beginning of Operation Plum Bob, atomic test site, Nevada. The tests are scheduled to continue into September.					Probably a warhead for small rockets or missiles. Yield about 10,000 tons of TNT.
					May 31	Christmas Islands.	2d hydrogen bomb exploded by the British.

LETTER OF TRANSMITTAL

CONGRESS OF THE UNITED STATES,
Washington, D. C., June 12, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Washington, D. C.

DEAR MR. DURHAM: We would like to thank you for publishing the hearings on naval reactors development held on March 7 and April 12, 1957, by the Research and Development and Military Applications Subcommittees of which we are the chairmen, and ask if you would print this letter as a preamble to the record.

The efforts of the Naval Reactors Branch of the AEC together with its field offices and contractors have given our Nation world leadership in the development of atomic power for naval propulsion. In no other area of military endeavor, either nuclear or conventional, is our national leadership now so clear and pronounced. But today's leadership is not enough. We believe that a fleet of nuclear-powered underwater vessels capable of firing long-range missiles will ultimately decide the balance of world power and the maintenance of the peace.

The Naval Reactors Branch has also played a leading role in the development of civilian atomic power. With its industrial contractors it has been primarily responsible for developing the technology of pressurized-water power reactors. The country has, therefore, received a double dividend on money spent for naval nuclear propulsion. We have world naval leadership in atomic power and will soon have the civilian reactor at Shippingport, Pa. Unquestionably, the dollar value of these developments to American industry is many times greater than the Government's investment.

In our hearings we determined that the Naval Reactors Branch is enjoying the full support and cooperation of the Atomic Energy Commission, and the observations we make below should not be construed as criticism. They are offered in a constructive sense and for the most part call for the continuance of existing practices. We consider the remaining suggestions refinements of existing practices.

We feel confident that our colleagues on the Joint Committee join us in expressing every confidence in the Naval Reactors Branch under the direction of Rear Adm. H. G. Rickover, United States Navy.

In connection with our review of the role and activities of the Naval Reactors Branch, we believe the following observations are appropriate:

1. The wisdom of continuance of the placing of central direction of the program in the Atomic Energy Commission and the Navy in a single official has been amply shown. Our hearings consistently dem-

onstrated that Admiral Rickover has always accepted personal responsibility for the program under his direction—including responsibility for technical setbacks.

2. This unique organizational arrangement whereby the Office of the Chief of Naval Reactors Branch of the Atomic Energy Commission and the Assistant Chief of the Bureau of Ships for Nuclear Propulsion is combined in the same person has prevented much duplication and is in keeping with the purposes of the Atomic Energy Act of 1946 and 1954. The present organizational arrangement for naval reactors work has proved economical, efficient, flexible, and capable of doing the job, and should be maintained. Any suggestion of establishing duplicate functions in the Department of Defense should be rejected in the interests of economy of manpower and appropriated money. The system employed by the Naval Reactors Branch in the selection, training, and assignment of personnel should also be continued. Officers and civilians are assigned to jobs on the basis of ability and not rank. We are assured that the test of selection is—who can best perform the job?

3. The research and development philosophies which have been employed by the Naval Reactors Branch should be maintained. We observed that this approach is neither attached to "beyond the horizons" concepts nor affixed to mere reproductions of successful models. A proper balance has been found in that the developmental goals are fixed at a level above present anticipations of success but not so far beyond them that accomplishment is not possible.

4. The Atomic Energy Commission should consider the immediate assignment to the Naval Reactors Branch of the development and construction of a new civilian reactor concept. With the prospective completion of the pressurized water reactor at Shippingport, additional time and attention could be given to a new reactor type. We specifically call attention to the desirability of assigning the development of an advanced type gas cooled reactor, and point out that some years from now the knowledge acquired in the development of a gas system may have application for ship propulsion.

We were pleased with the assurance we received from the Chief of Naval Operations that Admiral Rickover has direct access to him in connection with the naval reactors effort. We feel sure that in light of the importance of this work that this same access is available to him in all departments in the executive branch of the Government.

We are confident that the Commission and the Navy recognize the importance of these programs in furthering the interest of the national defense and security and will not permit doctrinaire administrative practices to interfere with the effort.

Quite often in carrying out our duties as Members of the Congress we must be critical of the activities of the agencies in the executive branch of the Government. We therefore take great pleasure in commending those who have been responsible for the success of the naval reactors program.

Sincerely yours,

MELVIN PRICE,
Chairman, Subcommittee on Research and Development.
HENRY M. JACKSON,
Chairman, Military Applications Subcommittee.

JOINT COMMITTEE ON ATOMIC ENERGY,
Washington, D. C., June 13, 1957.

Senator HENRY M. JACKSON,
Chairman, Military Applications Subcommittee.
Representative MELVIN PRICE,
Chairman, Subcommittee on Research and Development.

DEAR SENATOR JACKSON AND MR. PRICE: I have asked the staff of the Joint Committee to have your letter to me of June 12, 1957, on the naval reactors program printed with the record of your hearings on the subject.

I fully endorse your comments and observations, for the work under Admiral Rickover is most vital to the United States.

Sincerely yours,

CARL DURHAM,
Chairman, Joint Committee on Atomic Energy.

CONTENTS

(A brief subject index will be found on page 101)

PROGRESS REPORT ON NAVAL REACTOR PROGRAM AND SHIPPINGPORT PROJECT

THURSDAY, MARCH 7, 1957

CONGRESS OF THE UNITED STATES,
SUBCOMMITTEE ON RESEARCH AND DEVELOPMENT
AND THE SUBCOMMITTEE ON MILITARY APPLICATIONS OF
THE JOINT COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The subcommittees met, pursuant to notice, at 2 p. m., in room F–88, the Capitol Building, Hon. Melvin Price presiding.

Present: Representatives Price, Durham, Holifield, Dempsey, Cole, Van Zandt, and Patterson; and Senators Jackson, Hickenlooper, Knowland, and Bricker.

Also present: Willard F. Libby, Commssioner, AEC; Thomas E. Murray, Commissioner, AEC; A. Tammaro, Assistant General Manager for Research and Industrial Development; L. H. Roddis, Jr., Deputy Director, Division of Reactor Development; Adm. H. G. Rickover, Chief, Naval Reactors Branch; Capt. James M. Dunford, Assistant Chief, Naval Reactors Branch; Bryan LaPlante, special assistant to the General Manager; Capt. John H. Morse, Jr., assistant to Mr. Strauss; Capt. W. B. Braun, representing Admiral Burke, United States Navy.

Staff members present: James T. Ramey, executive director; Messrs. Brown, Conway, Hollister, and Toll.

Representative PRICE. The committee will be in order. This is a joint meeting of the Subcommittee on Military Applications, of which Senator Jackson is chairman, and the Subcommittee on Research and Development, of which I am chairman.

The meeting today has been called for the purpose of hearing from the Atomic Energy Commission as to the current status of the projects under the Naval Reactors Branch and what progress we may expect in the future.

It is my understanding that Admiral Rickover is prepared to cover this matter for us and to answer any questions individual members may have.

Admiral Rickover, we would like to say how pleased we are to have you with us today. The committee has been very favorably impressed by the excellent contributions the AEC has made to the civilian power program through the naval reactors program. As Congressman Durham, the chairman of the Joint Committee, has publicly stated in the 202 hearings, the contribution has been outstanding.

We sincerely hope it will continue to be so in the future.

From the large number of models which you have brought with you and which we see in the room, it would appear that you intend

to cover a great deal of material. We will, therefore, turn the meeting over to you, Admiral Rickover, and you may proceed when ready.

STATEMENT OF ADM. H. G. RICKOVER, CHIEF, NAVAL REACTORS BRANCH, ATOMIC ENERGY COMMISSION

Admiral RICKOVER. Thank you, sir. This is the first time I have been at the committee since Carl Hinshaw died, and as a witness who has appeared here many times and who has been questioned by him very pointedly, I would like to express my sincere regrets that he is not with us here today so he could continue to ask so many pointed questions, as he always did.

Although I used to accuse him of being for the Air Force, he was really for everybody, and helped us in the Navy a great deal.

Representative PRICE. We certainly miss him on the committee in many ways.

Admiral RICKOVER. There are a number of activities in the naval program that have no names. I wonder if it would be desirable to name one of these activities after Carl Hinshaw?

Representative PRICE. I think it would be very desirable, and I hope you can find a suitable one to dedicate to his memory.

Admiral RICKOVER. We can find one. I talked to the chairman of the board of Combustion Engineering. They have their new plant at Windsor, Conn., and I think they would be very happy to name it the Carl Hinshaw Laboratory. There are other places too.

If the committee cared that this be pursued, I would be happy to do so.

Representative PRICE. I think the committee would be very happy to have you do it. I think also the first flying prototype of a nuclear aircraft would be a fitting memorial to Mr. Hinshaw.

Admiral RICKOVER. But an aircraft carrier might come first.

Representative PRICE. You may proceed, Admiral, with your presentation.

Admiral RICKOVER. It has been frequently said that the things that have been done in the naval program have been done by a combined industry, AEC, and Navy team. I consider the Joint Congressional Committee to be an additional member of that team. I know and you people know that you have been just as much behind our program as anyone else and I very sincerely feel that way, because I know that without all your help and your confidence during the time when there was not anything to show you, without your backing we would not have progressed as far as we have.

The models I have in this room today are some examples of that, because all of them have either been built or are under construction

I will touch briefly on the naval program and then tell you about some of the advanced things we are doing, as you requested, sir.

The *Nautilus* was refueled about a week ago. She will again be ready for operation in about a month. Her first core ran for 62,500 miles, of which about 37,000 miles were fully submerged. The core lasted longer than we expected.

The new core will last even longer. This additional core life is being obtained without any increase in cost of manufacture, so that in effect when we increase the life of the core we cheapen it; even though it may cost the same it cheapens it in that proportion.

Representative PRICE. Would you mind comparing that performance with the performance of a conventional submarine.

Admiral RICKOVER. Yes, sir. During this process of steaming 62,500 miles, a conventional submarine having equal horsepower would have burned about 2,170,000 gallons of oil, the amount contained in 217 tank cars, with a length 1.7 miles long.

Representative VAN ZANDT. How long?

Admiral RICKOVER. 1.7 miles long; 2,170,000 gallons. That is the equivalent amount of fuel oil a conventional submarine of that power and having the same displacement as the *Nautilus* would have burned. The new core should do better than that.

Representative COLE. What is the price of that?

Admiral RICKOVER. Diesel oil, I think, costs about 8 to 10 cents a gallon, something on the order of 9 cents. I am not absolutely certain of the cost.

Representative VAN ZANDT. Are you good at arithmetic?

Admiral RICKOVER. That would be about $200,000 worth of oil. It is not much in cost. I do not want to leave any impression with this committee that to run a nuclear-powered vessel is cheaper than a conventional one. It is not. Because the amount you save by the oil is insignificant compared to the cost of the reactor core on present prices.

However, the cost of cores is coming down.

I do not want to create any wrong impression on that score.

As I stated, the new core will have more life. We already have evidence of that. As I stated, the *Nautilus* will be ready for sea in April and her core should be good for more than 2 years without refueling.

Representative VAN ZANDT. What did you find on the inside of the reactor, as far as the metals that were employed? I am thinking now of the pipes and so forth.

Admiral RICKOVER. We looked inside the pressure vessel of the *Nautilus* after the core was removed and it was shiny and clean. We found nothing wrong. During the refueling operation no one was irradiated beyond 300 milliroentgens a week, which is the normal permissible by AEC standards—no more irradiation than is allowed in an AEC laboratory for a week. I think 250 milliroentgens was actually the maximum dose.

Representative VAN ZANDT. In the beginning you recall in the design of the *Nautilus* there was piping used that could not take the pressure. I am wondering what did you find in conection with that redesigning?

Admiral RICKOVER. There was no faulty pipe found. A mistake had been made during the building period in 1954. Some wrong pipe had been used in the steam system instead of the pipe which had been specified, but this was corrected before the ship ever went to sea.

At Arco—perhaps I had better talk for a few moments on what we are doing there. We are using that installation as a training facility and as a test facility for trying out new reactor ideas.

For instance, it was there we tried out fuel elements that gave us increased life.

We have trained about 60 officers and about 500 enlisted men on the submarine prototype at Arco. Just before I came up here today,

I heard that we are losing 6 percent per year of all the enlisted men in the nuclear program because they become officers; 20 times as many enlisted men in our program become officers as do in the rest of the Navy.

I am not happy about this loss, but it is good for morale, and it is good for the Navy.

Of course, not all of the credit belongs to our training program. Our selection procedure obtains a high class of people for the program. That helps account for it. It does pose a serious problem to lose so many men, but it results in overall good to the Navy.

Representative VAN ZANDT. What about the initial selection? Have you an unlimited reservoir to select from as far as enlisted personnel is concerned?

Admiral RICKOVER. Enlisted personnel for the program are selected by the forces afloat, but we have fairly strict requirements, such as 4 years obligated service, and graduation from high school. Also a good record and above-average ability and intelligence.

We have, first, a 6 months' course at the submarine school in New London. This is a special course where we teach physics and mathematics, and various nuclear courses. After the course at New London the men are sent to Arco for another half year. There they learn how to operate and service the plant. They are then assigned to nuclear-powered ships.

The officers for the nuclear propulsion program are designated by the Bureau of Naval Personnel. They are also given 6 months' theoretical training and 6 months at Arco. Their course is much more difficult than that the enlisted men. All of the officers and a number of the enlisted men qualify as chief operators before they complete the course. This is a very difficult thing to do, but it assures us of having competent people for our nuclear plants. Admiral Holloway, our Chief of Naval Personnel, has been very farsighted in understanding our problems, and has gone out of his way time and again to help us. Without his help we could not have accomplished what we have.

Representative COLE. How does the enlisted man get to be an officer?

Admiral RICKOVER. The Navy conducts examinations twice a year.

Representative COLE. What additional training does he have in order to become an officer, none?

Admiral RICKOVER. No, sir. When he is selected for officer he is then sent to an officer candidate's school. There he is given special training for about 6 months and, if he completes the course, he is commissioned.

Representative COLE. Is he a general officer, a line officer?

Admiral RICKOVER. Yes, he becomes a line officer, an ensign.

The year's training we give the sailors and officers in our program is very valuable. I have been told that to qualify as Chief Operator at our prototype at Arco is several times as difficult as it is to qualify for command of a submarine.

It requires about 1,000 hours of practical work for this qualification, and this is in addition to all of the study they do. They must become adept in all phases of reactor operation, particularly in everything that pertains to safety. Even the commanding officers work 16 hours a day, 7 days a week at Arco.

I will say no more on training, except I must add that the facility at Arco is most valuable from this standpoint. We have no better training facility in the Navy than we have there and it is absolutely essential for the future of nuclear power in the Navy that we train the people there, on a real plant, a live one, because we do not want any accidents to happen. We want them to know the plant inside out. I am proud of the fact that all of the officers and men in the program are outstanding. They are all a marvelous group of very fine people and I am sure that ultimately they will be the leaders in the Navy.

Senator HICKENLOOPER. May I ask a question of Admiral Rickover?

Do you have a rough approximation of the cost of the operation of the *Nautilus* so far as fuel is concerned? Take the 2,170,000 gallons of fuel oil. That cost compared with the cost of nuclear heat, the core, its replacements, and utility of the core.

Leave out the plant itself.

Admiral RICKOVER. It is rather meaningless to say we are saving money. What we are getting is a profound military advantage.

Senator HICKENLOOPER. I understand that, but I just wanted to get some approximation.

Admiral RICKOVER. This gets into the problem of the cost of atomic power. At the present time, and for the next 10 years, I do not believe atomic power can compete economically with conventional power. We are still in the development stage. We are still learning how to develop and manufacture nuclear cores.

At Shippingport the cost of the power will be between 55 to 65 mills per kilowatt.

I believe it is rather farfetched to expect nuclear power to be competitive with conventional power for the next few years. I do not say it will not happen, but not today, not for the next few years.

Representative VAN ZANDT. What was the cost of the *Nautilus* per kilowatt?

Admiral RICKOVER. In wartime the cost was about 8 cents per kilowatt-hour on a conventional submarine.

Representative VAN ZANDT. You said 8 cents?

Admiral RICKOVER. That is 80 mills. But if you took into account the cost of convoys and fueling stations and other factors, I am not so sure that from an overall standpoint you would find, taking all the other factors into account, that nuclear power on a warship is more expensive than conventional fuel. I am not talking now about the military advantages we get from the use of nuclear power. Nuclear power gives us ships that can go at high speeds and can stay submerged for days at a time.

One of the things we did with the second core at Arco was to run it for 66 days and nights continuously at full power. The lines on this map [indicating] show the distance a nuclear submarine would have steamed under the same circumstances, on a full-power nonstop run. It would have run once around the world and back to New London, and without stopping set out again and go around the world on a northern route. That is a longer continuous run at full power than a plant of any kind, land, sea or air, has ever made. In contrast, the Navy acceptance trial at full power for a new ship is 4 hours. This plant ran for 1,700 hours continuously at full power.

Representative PRICE. Which reactor is that?

Admiral RICKOVER. It is the one at Arco, and is similar to the one that has just been installed in the *Nautilus*.

Representative PRICE. Similar to the *Nautilus?*

Admiral RICKOVER. Similar to the one that has just been placed in the *Nautilus*.

Representative PRICE. The new *Nautilus* reactor?

Admiral RICKOVER. Yes, sir.

Representative VAN ZANDT. The *Nautilus* is equipped with auxiliaries?

Admiral RICKOVER. Yes, sir.

Representative VAN ZANDT. Both diesel as well as batteries?

Admiral RICKOVER. There are two 300-horsepower diesels used for supplying auxiliary power in port. They are capable of propelling the *Nautilus* on the surface at slow speed if the ship had to do so in an emergency.

Representative VAN ZANDT. At any time during her life so far have you had to fall back on your auxiliaries?

Admiral RICKOVER. Yes, sir; we have fallen back on storage batteries for a short time, but Admiral Watkins, who is commander of the Submarine Atlantic Fleet, has told me that the *Nautilus* has operated with as great a reliability as any submarine he has in his entire force. She has not once failed to meet a planned operating commitment.

I understand you are going to have Captain Wilkinson in here next week to testify.

Senator JACKSON. Monday.

Admiral RICKOVER. He will come before Senator Jackson's committee, and I hope you ask him some of these questions.

The *Nautilus*, of course, has operated much more than any conventional submarine since she has been in commission.

Senator JACKSON. In order to get a proper projection of costs on the operation of the *Nautilus*, you would have to project the *Nautilus* into, say, 50 such ships.

Admiral RICKOVER. Yes, sir.

Senator JACKSON. And compare it with 50 conventional submarines with all the supporting elements, would you not, in order to get a fair overall operating cost?

Admiral RICKOVER. Yes, but Senator, you have a lot of intangibles in there, too. A war machine cannot be judged by cost.

Senator JACKSON. No.

Admiral RICKOVER. Cost is one factor. But a more important factor is, What can she do?

Senator JACKSON. In other words, the contribution she can make to our national security.

Admiral RICKOVER. I do not know how you are going to equate the operating cost with the military value.

Senator HICKENLOOPER. My question did not go to holding you down to dollars-and-cents cost. I want to get an approximation of comparison.

Admiral RICKOVER. Would you want me to get this information and file it for the record? I will be glad to.

Senator HICKENLOOPER. If it is at all reliable. I realize there are many, many intangibles involved.

Admiral RICKOVER. Yes, sir.

Senator HICKENLOOPER. You also have an experimental ship and have done a lot of experimenting with this thing, and I presume it would be very difficult indeed to get down to any accurate cost accounting on this thing. I just wanted to get some idea.

Admiral RICKOVER. I think I have given you a rough idea.

Senator HICKENLOOPER. Yes.

Admiral RICKOVER. I think the best way to sum it up is to state that the *Nautilus* is not a new type submarine; she is really a new weapon. I think you just cannot compare it with any conventional submarine. You would be comparing two dissimilar things. It is very difficult for most people, including people in the Navy, to realize, that a nuclear submarine is really a new weapon. We are going to be faced with the same problem in the Navy when we get the first nuclear-powered surface ship.

The next class of submarine after the *Nautilus* was the 578 class. This model [indicating] shows the *Nautilus*. It is 320 feet long and makes over 20 knots. It displaces 3,200 tons on the surface.

There are five of the 578 class. Four will be attack submarines and the fifth one will be a guided-missile submarine which is now being built at the Mare Island Naval Shipyard. Keels of all five have been laid. The first one, the *Skate*, will be launched in May at Electric Boat, and should be at sea about the end of this year or early next year.

This one [indicating] the *Skipjack*, is the latest type, with an *Albacore*-type hull. It has a single propeller.

The reason we went to a faster submarine was because soon after the *Nautilus* went out on her trials it became evident that for a submarine to remain effective against the most modern type of antisubmarine methods, she would have to make higher speeds.

Therefore, we designed this ship and she should be in operation about June of 1958.

Incidentally, the *Sea Wolf* went to sea this morning at 8 o'clock. Perhaps you would want to hear about the *Sea Wolf?*

Representative PRICE. Yes.

Admiral RICKOVER. I will get on that story now. I hope you do not mind me jumping around on this testimony.

Representative DURHAM. I would like to hear about the *Sea Wolf*.

Admiral RICKOVER. As you know, the *Sea Wolf* reactor uses sodium as a coolant instead of the ordinary water used in the *Nautilus* reactor. Sodium becomes about 30,000 times as radioactive as water. Furthermore, sodium has a half-life of 14.7 hours, while water has a half-life of about 8 seconds. As we went on with the testing of the *Sea Wolf* we found that even a very small leak in the heat exchangers would cause serious trouble. We went to full power on the *Sea Wolf* alongside the dock on August 20 of last year. Shortly thereafter she developed a small leak. It took us 3 months, working 24 hours a day, to locate and correct the leak. This is one of the serious difficulties in sodium plants. When you do have trouble, a considerable amount of time and expense is involved in correcting it because of the high radioactivity. We found that the trouble was a type of corrosion of stainless steel called stress corrosion; stainless steel has a tendency to become corroded by sodium. This means that unless the heat exchangers are absolutely tight and never leak there will be trouble.

We managed finally to fix the heat exchangers on the *Sea Wolf*.

We cut out some of the heat exchanger capacity which reduced the power about 10 percent. We also cut the superheaters out of the system which reduced the power another 10 percent. The *Sea Wolf* went to sea on the 21st of January, and she has been operating since that time. With the reduced power she makes about 90-percent speed.

I was on her during her first sea trials. She steamed about 800 miles, half of which were submerged. After operating for 4 or 5 days she went into drydock for structural repairs. This had nothing to do with the atomic powerplant. She got out of drydock and was at sea again for 8 to 10 days.

If a leak develops in a sodium plant on board ship—I am not talking about shore sodium-cooled plants—then it is quite serious to repair. The radioactivity must be left to decay, and repairs are lengthy and expensive.

But if you had a thimbleful of leakage in a sodium plant you probably could not run.

Senator BRICKER. What is the reason for adopting the sodium coolant?

Admiral RICKOVER. At the time we started on the nuclear propulsion program, sir, we went to two equivalent approaches. At that time, in 1947, we did not know which one would work. As a matter of fact, at that time we thought sodium had a better chance of working than water. Sodium had been chosen by General Electric for their power breeder at the Knolls Atomic Power Laboratory. Later on, when the Commission found that the design of the sodium-cooled power breeder was not going along well and the expense to build it would be too great, it was changed to a naval submarine project and we in the Naval Reactors Branch took it over.

No one knew at that time which would work better, and since atomic power was extremely important for the Navy we decided to follow the two approaches, but we did not know then which would be better. In fact, we were not then definitely sure that either one would work. Now that we have had the chance to operate both the *Nautilus* with her water-cooled plant, and the *Sea Wolf* with her sodium-cooled plant, it is obvious that water is much better than sodium for naval plants. All other nuclear ships, submarines and surface vessels, are being designed for water-cooled plants.

Senator BRICKER. What did you say the half life of sodium is?

Admiral RICKOVER. 14.7 hours.

Representative VAN ZANDT. What percentage of pressure have you lost?

Admiral RICKOVER. We have not lost pressure. We have lost heat transfer capacity. We have lost about 20 percent. The bypassing of the superheaters and the plugging of some of the heat exchanger circuits have reduced the heat transfer by about 20 percent.

Representative VAN ZANDT. Then you are working with 80 percent of capacity today.

Admiral RICKOVER. Yes, sir. But if we get more leaks we will have to plug additional circuits, and reduce the capacity some more.

Representative VAN ZANDT. What has that done to the speed?

Admiral RICKOVER. It has cut the speed 2 to 3 knots so far. Of course, the speed of a ship is not cut in proportion to the loss in power.

Senator Bricker, I think you have to recognize that if you want to get ahead with any game of this kind you have to take a chance. You do not know if it will work and if something is important you have to go ahead on more than one. You went ahead fully, experimentally, on both sides.

Admiral RICKOVER. Yes, sir. I did not consider the *Nautilus* a success until it was demonstrated that it worked all right for a long period of time.

Senator BRICKER. Is there any advantage in the sodium coolant at the present time that you know of?

Admiral RICKOVER. Theoretically sodium has advantages which may pay off in shore plants. You can get much higher temperatures and steam pressures, which means greater efficiency. Also it is possible to use lower pressures to circulate the sodium in the primary system. This means less pumping power.

For example, in the *Nautilus* we use high pressure in the primary system in order to keep the water as a liquid instead of boiling over into steam. On the *Sea Wolf* we use low pressure, just enough to force the sodium through the system. For this reason the pumping power in the *Sea Wolf* is only one-fourth that in the *Nautilus*.

Sodium has the advantage that it does not rust away the surface of material as water does. For this reason small particles of radioactive material do not get into the system and remain there for longer periods of time, and make access and maintenance difficult.

There may be advantages for sodium for shore-based atomic powerplants but I cannot see it for a ship. It is too dangerous for a ship.

After the *Sea Wolf* returned from her first trials she was docked at the Electric Boat Co. We then moored a conventional submarine alongside her and flooded the latter's ballast tanks to see how much of the *Sea Wolf's* radiation would carry through the flooded ballast tanks and into the ship. Even with the ballast tanks full, enough irradiation came through to the conventional submarine to give her crew in that vicinity as much radiation in 4 hours as is normally permitted for a week. Of course, in a while the radiation would be reduced a great deal because it has a half-life of 14.7 hours.

These are some practical problems we have learned about sodium plants. I am not saying these all apply to shore-based sodium plants. I am confining myself to ships. It certainly does apply to ships. As a result of this situation on the *Sea Wolf* and because the Navy is not building any more sodium-cooled ships, the Commission has decided to shut down the Mark A prototype plant at West Milton, N. Y. In order to save money, we are shutting it down. There is a letter in process which states this, but which may not yet have reached the committee.

Representative DURHAM. The letter has been received today.

Admiral RICKOVER. I wanted to mention it.

Senator BRICKER. That will be the only sodium reactor, then, in the whole fleet of submarines.

Admiral RICKOVER. Yes, sir. We intend to keep on operating the *Sea Wolf* as long as we can. If we get another sodium leak we will analyze it and see how expensive it is going to be to repair it. If it is not too expensive we will repair it and keep on operating because we can get very valuable tactical information today from any nuclear-

powered ship. We are not planning to have any more sodium-cooled ships in the Navy at the present time.

Representative VAN ZANDT. Have you had any personnel problems as far as exposures?

Admiral RICKOVER. No, sir. The maximum exposure we have had in the *Nautilus* per year in 2 years of operation is about 2 roentgens. That is the total for the year. The average radiation of people in the *Nautilus* during the 2 years of operation has been about 200 milliroentgens a week, or two-thirds of what is permissible in AEC laboratories.

Representative DURHAM. That West Milton plant could be used for civilian power; could it not?

Admiral RICKOVER. Actually, since it first started up we have gotten out of that plant about 2¼ million kilowatts of electric energy, of which about three-fourths of a million was sent out over the Niagara-Mohawk system. The rest was used on the site. But there is not much income from the sale of this power, sir. The cost of operating the plant is pretty high. That is, you get a few thousand dollars for the power but it costs very much more to operate. That is not a good financial deal for the Government.

Representative PRICE. It is not a good prototype for a civilian reactor.

Admiral RICKOVER. No, sir; because a civilian reactor would use an entirely different type of heat exchangers and an entirely different reactor system. A civilian plant would also be much larger. We are expecting to use the sphere in which the *Sea Wolf* prototype is contained for a destroyer prototype. I will discuss this in a little while.

Senator JACKSON. While on reactors, what about the gas-cooled reactor; what is the situation there?

Admiral RICKOVER. For a naval vessel?

Senator JACKSON. For propulsion.

Admiral RICKOVER. We made studies of gas-cooled reactors in the early days before we decided on sodium or water or gas, and we came to the conclusion first that a gas plant would be heavier and take up more space, and second, there was no assurance that there would not be leakage of radioactive gas into the ship. You may be able to tolerate such leakage in a shore plant. Since we do not know yet how to make any gas system tight, I do not consider it practicable for a ship. You are always taking the chance that radioactive particles may carry over from the reactor into the propulsion system or that radioactive gas leaks into the atmosphere. You can irradiate the crew this way.

A plant using air as the coolant would be so large it is impracticable for a warship where space is limited. Therefore, you have to go to a closed cycle plant. This type of plant should be tried out ashore and on other types of ships before it is tried in a naval vessel.

The Maritime Commission and the Reactor Development Division are having studies made at the present time of gas-cooled reactors for marine application. My personal opinion is that it will take a number of years before there is a sufficient degree of reliability to permit us to go ahead with a closed cycle gas-cooled plant in a naval vessel.

You see, our program consists not alone of reactors but also of ships that are appropriated for by Congress and we have to meet a date, and

ships have to work. That is a difficulty I labor under. That is demonstrated by all of these models. Everything you see here either has been built or is being built. They are not pictures of reactors. They are items that have been or are being designed.

Representative PRICE. Admiral, it would be advisable if you would just specifically describe to us the different types of reactor programs you are engaged in at the present time and then we might direct our questions toward those various types of reactors that you are actually working on.

Admiral RICKOVER. Yes, sir.

Representative PRICE. And then discuss those you think might be valuable to put into future programs.

Admiral RICKOVER. I discussed the Nautilus and the Seawolf. I would like to go on because I have so much more to say. I have talked about the 578 class. There are four 578-class attack submarines and one guided missile submarine.

These are the 585 class [indicating], which are single screw. There is 1 in the 1956 shipbuilding program and 6 in the 1957 shipbuilding program.

Incidentally, it may interest you to know this: I just checked up the amount of kilowatts we are going to have in nuclear-powered ships in the Navy. Projecting the present rate of nuclear shipbuilding we would have by 1963 about 1½ million kilowatts of power in operation and an additional million kilowatts in ships under construction. So we might have either in operation or under construction by 1963 about 2½ million kilowatts of atomic power in the Navy.

Senator JACKSON. 600,000 more than Grand Coulee.

Admiral RICKOVER. Yes, sir.

Representative VAN ZANDT. What is the mission of the Albacore type?

Admiral RICKOVER. It is an attack submarine. It can carry standard torpedoes. But its nuclear plant can also be used for guided-missile submarines; there will be three in the 1958 program. There are also two other types of nuclear submarines.

One type, and the one I consider very important, is the radar picket submarine. The reactor plant is being designed by the Knolls Atomic Power Laboratory of the General Electric Co. It will have two reactors. The submarine will displace about 5,800 tons on the surface and 8,000 tons submerged. It will be by far the largest submarine ever built.

Representative DURHAM. Is there any difficulty in procuring the raw material?

Admiral RICKOVER. Yes, sir. You mean fissionable material?

Representative DURHAM. Not only that—zirconium.

Admiral RICKOVER. I am glad you mentioned that. I might as well say right now and get into that—in order to carry this naval program through we have had to build up an industry. The first type of industry we have had to build up is zirconium. We started several years ago when the Atomic Energy Commission made a contract under competitive bidding and selected the one which offered the best terms, Carborundum Co. They contracted to supply 325,000 pounds of sponge zirconium a year for 5 years at a cost of about $12½ a pound.

Last year in looking into our prospective program we decided that by late 1958 we would have to have enough additional zirconium

sponge-making facilities for 2 million pounds of sponge a year. An arrangement was worked out between the Navy Department and the Atomic Energy Commission whereby the Atomic Energy Commission made the contracts, the Navy supplied the money, and we brought three new organizations into the program. They were selected on the basis of competitive bidding to see which ones offered contracts which were to the best financial interests of the Government. One of those brought in was the National Distillers Corp. They are putting up their own plant and developing their own process to make a million pounds of zirconium sponge a year for us.

The National Research Corp., is another contractor with whom we made a 5-year contract. I think they are building facilities to make a minimum of 700,000 pounds a year for us by still another process.

We made another contract with the Carborundum Co. to supply us from another plant which would produce for us about 600,000 pounds a year for 5 years. In addition to these contracts we made one contract with the Wah Chang Corp. to operate the Government-owned pilot plant we had at the Bureau of Mines in Albany, Oreg. Still another source of supply is the Hugo Neu Co. from whom we expect to get Japanese zirconium. We expect to get zirconium sponge under our new contracts for about $6 to $7 a pound, instead of about $12 as at present.

The companies who have these contracts, in addition to putting in enough facilities for carrying out the naval program, are also putting in capacity to take care of anticipated civilian reactor needs. We paid $300 a pound for sponge when we started out in 1948. It was only available in gram quantities at that time.

Senator BRICKER. What are the civilian uses?

Admiral RICKOVER. In addition to reactor use, it is used in the electronic industry for clearing out air and gases and so on in electronic equipment. It certainly will be used in civilian atomic powerplants, because a number of the organizations who are designing atomic powerplants are using zirconium as a basic construction material.

It also should find considerable use in the chemical industry because zirconium is much less corrosive than stainless steel at higher temperatures. It is far better.

Representative DURHAM. Does your program take the entire production from the companies you mentioned?

Admiral RICKOVER. It is currently taking nearly all of the entire production. But, as I said, the new companies are installing capacity to meet the naval requirements, and also other reactor requirements, as well as various commercial uses. But we are paying for our requirements. The other people who are designing reactors which use zirconium have not put up any money, as far as I know, to get the zirconium they will need. The Navy has put up its own money for this. The money comes from naval construction funds.

Representative DURHAM. In other words, the civilian reactors cannot depend on this production.

Admiral RICKOVER. These companies are building more capacity than is needed for the naval plants, so there should be zirconium available for civilian reactor plants.

It might interest you to know that in every one of these cases the companies put up their own money for their plants. We did not finance their plants; we did not recommend that they get a certificate of necessity. The contracts were made on a strictly commercial basis. From here on out we expect to be able to buy zirconium in the regular market.

The next important thing we had to do was to get more facilities for making reactor cores.

Our practice right now is to have our laboratories develop and make the first core of a type, and thereafter to put it out on competitive bidding.

For example, take the core for the 578-class submarines. About 8 months ago we asked for competitive bids for 5 of these cores. We now have a number of companies that have equipped themselves at their own expense to manufacture cores on a competitive basis: Westinghouse Electric Corp.; Olin-Matheson Co. at New Haven, Conn.; Metals & Controls Corp. at Attleboro, Mass.; Combustion Engineering Co. at Windsor, Conn.; and Babcock & Wilcox Co. at Roanoke, Va. Each company has put in at least $3 million of their own money, again with no certificate of necessity, for the necessary facilities. They have taken contracts for these cores on a competitive basis. On this basis we were able to order these cores for less cost.

We have just put out proposals for seven cores for another type of submarine. These will all follow the design of the first one, which is a developmental job, and which was designed and built at the Bettis Laboratory. All will be made in commercial facilities and competitively. We are getting industry to make as many other components as possible for our nuclear plants.

So that even as we are going along with the design of different types of plants we are establishing the industry necessary to carry the production along.

Insofar as components for nuclear powerplants for these ships are concerned—I looked this up just the other day—we have placed orders for $29 million for nuclear parts competitively—this is about 86 percent of what we are buying now on competitive lump-sum bidding, and only 14 percent is bought on cost-plus basis. This consists of items such as controls where the development is still in progress and sources of supply have not yet been developed. I am not talking about the steam machinery. That is all bought competitively. I am talking about the nuclear part. Even for the nuclear parts of the plant 86 percent is being put out on competitive bidding right now.

Representative Holifield. Private companies are doing it?

Admiral Rickover. Yes, sir; private companies are doing it. We do not want laboratories or plants operated by the Government to do it. We do not want to keep on building up Government's facilities. Private industry is doing it. I think you would be amazed if you really knew how extensive this private manufacture has grown.

Representative Durham. Do you think they are qualified?

Admiral Rickover. Yes, sir; we have taught them and supervised them, and we have had them send their people into places such as Bettis and the Knolls Laboratory where they are taught how to do it. Our people teach them how to do it. We help them set up their factories. We start them off by having them make small pieces. Before we assign them contracts for large items we assure ourselves that

they are capable of doing it. I do not have much concern about this at all.

Representative HOLIFIELD. Do you have any trouble getting private companies to bid on these different components?

Admiral RICKOVER. Not on reactor cores. We have difficulty with things like valves because they, as well as many other items, are very special. They have to be made leak tight, and they require a great deal of engineering. As long as we have an economy where people can get lots of business by doing conventional stuff not too many want to get into this special field. More companies would rather use their engineering staffs on conventional items because they can make more money that way. But those who look to the future know that this is good business to learn the new techniques which are going to be necessary if they are to remain competitive tomorrow. It is these forward-looking ones who are getting into our business. We have really had to fight with people in many cases to take our orders. It has not been easy.

Representative PATTERSON. Who pays for tooling on special valves?

Admiral RICKOVER. They do. We are trying to get this program into industry as fast as possible—to buy it like a loaf of bread.

Representative PATTERSON. You could not expect any manufacturer to put a special gear into a plant where he is going to make only 200 or 300 or probably even 2.

Admiral RICKOVER. Yes, sir; I do.

Representative PATTERSON. You expect him to do that?

Admiral RICKOVER. Yes, sir.

Representative PATTERSON. And have them pay for the tooling?

Admiral RICKOVER. Yes, sir. Sure. Why not?

Representative PRICE. Are they doing it extensively?

Admiral RICKOVER. Yes, they are.

Representative HOLIFIELD. Do they do it at a loss to themselves?

Admiral RICKOVER. Look, next year we are going to have about $50 million worth of reactor core business alone. It is like a fuel business. Once you get a ship in the water with a core you have got it there 3 or 4 years, then you have to take the core out and put a new one in. It is like the oil business.

Representative PATTERSON. Then do you go back to the original vendor you did business with——

Admiral RICKOVER. Competitive bidding.

Representative PATTERSON. Again?

Admiral RICKOVER. Mr. Patterson, that is what I thought Congress wanted us to do.

Representative PATTERSON. I am just asking the question. If you can get them to do it, fine, but I do not see how you can get the manufacturer to do that.

Admiral RICKOVER. We do.

Representative HOLIFIELD. They include the cost of that.

Admiral RICKOVER. Sure. It is going to be charged off. They have to charge it off over a reasonable period of time just as they do on any other venture, but I think we have babied a lot of people in this country too long with the glamor of atomic energy, and I think as soon as possible we have got to get down to do it like any other business.

Representative VAN ZANDT. Can we talk about some dollars and cents here?

Admiral RICKOVER. Yes. May I take a few minutes for the other ship?

Representative PRICE. Did you cover each one of your individual programs that you are working on? Can you cover that specifically and then we will ask questions?

Admiral RICKOVER. Yes, sir, in only a short time.

I have covered these three types of submarines and the large radar picket submarine—which can operate either as a surface ship or as a submarine. It is designed to go along with a carrier task force.

Representative COLE. Why do you have two reactors?

Admiral RICKOVER. In the first place, if there were only one you would have quite a large monster, and if that one went out you would have a valuable ship which costs more than $100 million in a helpless condition.

It is like any other important ship; you install more than one plant. The two plants are exact duplicates.

Representative VAN ZANDT. Is that an exorbitant cost?

Admiral RICKOVER. It is a high cost, but it is for the first one. Follow ships will be cheaper. I will give you the cost of every one of these ships in a moment, sir.

The last type nuclear submarine plant we are designing is for a hunter-killer submarine, a type which we could use in large numbers.

This represents another departure from our previous practice. Combustion Engineering has put up their own money for all of their facilities at their Windsor Laboratory. Not a penny of Government money has been used in their laboratory facilities. They have built and paid for all their own critical experiments. They have not only done all these things at a cost of about $10 million, but they have also put up $3 million of their own money to assist in the research and development of this submarine project. The prototype for this plant is now being built on land which Combustion Engineering has let us use near their laboratory at Windsor, Conn.

The Electric Boat Co. is building the prototype for Combustion Engineering, and there is a corresponding submarine in the 1958 shipbuilding program. We are building as small a reactor as we can for this horsepower to keep the ship small. It will be as quiet as possible. I have now covered all of the nuclear submarine types.

There are three other types of ships—surface ships. First we have the aircraft carrier, for which Congress last year authorized the Navy to start buying the machinery—about $21 million to start manufacture of both the conventional and the nuclear machinery.

The nuclear-powered aircraft carrier will have 8 reactors, 2 reactors per shaft. The old battleships such as the *California* and the *West Virginia* developed 32,000 shaft horsepower or about 22,000 kilowatts altogether. This ship will have an auxiliary plant which will use more power than the main propulsion plants of the battleships of the last World War.

I am not going into the military characteristics of the carrier. I am sure Admiral Burke, when he testifies, will do a better job on that than I can. I will just talk about the technical aspects. As I mentioned before, the Navy expects to ask for one of these each year, starting with the 1958 shipbuilding program.

Another surface nuclear powered ship is the cruiser. This is the one which Secretary of the Navy Thomas recently named the *Long Beach*. It will displace about 14,000 tons. It will carry a considerable number of guided missiles.

It uses, in general, the same type of reactor as the aircraft carrier. There will be two reactors in this cruiser. The keel for the *Long Beach* will be laid in less than a year, and she should be completed late in 1960. This ship is being designed, and will be built at the Quincy, Mass., shipbuilding yard of the Bethlehem Steel Co. The reactors are being designed at the Bettis plant of the Westinghouse Electric Corp.

The last ship in the program is a frigate.

At the present time the Navy is mostly depending on destroyers for antisubmarine warfare, but our destroyers when they make high speeds, have to be refueled at short intervals. This creates an intolerable situation because they cannot carry enough fuel to operate for adequate periods of time at high speeds without refueling. We found that out when we sent the *Nautilus* out to be attacked by the destroyers. The destroyers would go out and operate with the *Nautilus* and have to go back to port to refuel if they ran at full speed too long a time.

The AEC has assigned a project to the Knolls Atomic Power Laboratory to develop a powerplant for a frigate. We are trying to design the machinery plant with as low a weight as possible. Work on the frigate reactor design has just been started. I am not sure whether the committee has as yet been notified about it.

Mr. RODDIS. I do not think the letter is here yet.

Admiral RICKOVER. Possibly it has not gone out of the Commission yet.

To sum up, the Navy's nuclear propulsion program consists of the *Nautilus* and the *Sea Wolf* which are experimental types. Then we have the 578 class plant. Following that one we have the *Albacore* hull type which can be used either in an attack submarine or in a guided-missile submarine. Next there is the radar picket submarine which can accompany a carrier task force, and finally there is the hunter-killer submarine. For surface ships there are the three types: aircraft carrier, cruiser, and frigate.

So with the types of nuclear propulsion plants we are now working on we envisage being able to power any important naval vessel. This can be accomplished by using one or more of the reactor plants I have described. We are right in the middle of a vast program for changing our Navy.

A most important submarine is the one with two reactors. Its propulsion plant can also be used for large submarines carrying ballistic missiles. In fact, we had this in mind from the very first. It was changed over from the original concept of a missile-carrying submarine to a radar picket submarine because the submariners did not like it. They were not smart enough then to see the possibilities of such a submarine, and so they did not back it. But the surface ship people saw its utility, and backed it. That briefly describes our program.

I have mentioned the fact that we are getting industry into our program, and I should like to elaborate on that.

Representative VAN ZANDT. The Congress appropriates, do they not, to the Navy and its shipbuilding program for this nuclear powered construction; is that right?

Admiral RICKOVER. Yes, sir.

Representative VAN ZANDT. Is that money positively spent on the nuclear powered ships?

Admiral RICKOVER. Yes, sir.

Representative VAN ZANDT. Can it be diverted?

Admiral RICKOVER. No. The Navy really wants atomic powered submarines and the Navy definitely does not divert any money from nuclear submarines.

Representative VAN ZANDT. A few years ago surely they had a tendency to divert some of this money to conventional type construction. Now is it different?

Admiral RICKOVER. It is different now. The thing that holds us up from going even further in nuclear power in the Navy is that we have got to prove some of these designs. You people always ask the question, "Why do you build any other ships, now that you have the nuclear power?"

You have to put yourself in Admiral Burke's place. He has commitments he must meet today in the Near East, and he has not got the fine nuclear-powered ships. He has got to have ships today; he cannot just obligate all his construction money on the nuclear-power program. Perhaps a generation from today everybody will say, "They were damn fools for not having done it," but the people who may say that will not have been faced with the problems that we are faced with, those of us who have some responsibility are faced with.

Representative VAN ZANDT. From an operational standpoint, when will the nuclear-powered ships start to phase into the fleet?

Admiral RICKOVER. The *Nautilus* and *Sea Wolf* are now at sea. The first one of the 578 class submarines will be completed about the end of this year. After that there will be a new ship about every 6 months. About 3 submarines should be out in 1958. As you know, a total of 15 submarines have been authorized for construction. I should mention that we have also spread the base for ship construction for nuclear-powered ships. We now have two more commercial submarine building yards besides Electric Boat.

The Ingalls Shipbuilding Corp., in Pascagoula, Miss., and the Newport News Shipbuilding & Dry Dock Co. have been awarded contracts for building nuclear-powered submarines. This is a very fine thing because we will now have three commercial shipyards to build nuclear-powered submarines. Since there will be a large number of nuclear-powered submarines, we will be able to increase the design talent available. It will also give us an opportunity to get competitive bidding on submarines instead of always going on a negotiated basis or on a cost-plus-fixed-fee basis. In fact, the first nuclear submarine contracts awarded to Ingalls and Newport News were on a fixed-price basis.

So, you see, we are trying, as far as possible to get out of the system we have been using of paying a man whatever it costs him to do the job; instead to give him an incentive for doing it efficiently.

Representative PRICE. Are you on a competitive-bid basis now on the allocation of submarine contracts?

Admiral RICKOVER. Yes, sir. The last 4 nuclear-powered submarines were awarded, 1 to Electric Boat, 1 to Newport News, and 2 to Ingalls. The three companies submitted bids, and the submarines were awarded on a fixed-price basis. It is not yet 100 percent pure competition, sir, but pretty close to it.

In a fixed price, the Navy, I think, paid roughly about $40 million per submarine.

Representative DURHAM. Has there been any cutback on the program?

Admiral RICKOVER. No, sir.

Admiral RICKOVER. There were six in the 1957 program. There will be four in the 1958 program.

Representative PRICE. I know only four are proposed in the 1958 program.

Admiral RICKOVER. Only four are proposed in the 1958 program. That is correct, sir.

Representative PRICE. Has there been any cutback financially to your program.

Admiral RICKOVER. Well, I have not gotten as much money as I could use, but I think any witness you get up here would tell you that.

Representative PRICE. Did you get what you asked for?

Admiral RICKOVER. I got what I asked for from the Commission. I did not from the Navy. I get only a small portion of my development money from the Navy. I think you understand that without the support of the Atomic Energy Commission, and the freedom with which we can operate in the AEC, we would not have any nuclear-powered naval vessels today. The AEC budget contains all that I asked for this year. However, the naval program is advancing so rapidly that it appears now we could use 9 to 9½ million dollars more of AEC funds.

I want to make it clear that the Commission has budgeted for the money I asked. I do not want any misunderstanding on that score.

Representative COLE. Why did you say the Navy would not?

Admiral RICKOVER. The Navy in the early days did not put much money into the program. They are still not putting in as much money as I need.

Representative COLE. So many ships in that many years does not look like that.

Admiral RICKOVER. I am talking about research and development funds, not construction funds. Today in fiscal 1958 I am getting $86 million from the Atomic Energy Commission in research and development. I am getting about $11 million from the Navy. I tried to get $20 million from the Navy and could not, and that set us behind.

Senator JACKSON. You were cut almost $10 million.

Admiral RICKOVER. I was cut about $7 million in the Navy. I mentioned this to Admiral Burke the other day. He is going to help us as much as possible. But you realize that our major support in research and development comes from the AEC. Furthermore, no one else has as fine a committee to deal with as you people. I mean that. I am not just joking. Your committee has been a great support. Without this committee the Atomic Energy Commission could not possibly fare as well as they have, nor could the naval program have fared as well.

Representative COLE. Was it because the Navy did not want ships?

Admiral RICKOVER. Not ships. I am talking research and development.

Senator JACKSON. I think for the record it should be said that 2 years ago as a result of the work of this committee, Admiral Carney dropped one of his conventional submarines and added an atomic one. But there has been a lag, there is no doubt about it. There has been hesitation to take on something new. I think it unfortunate that just 2 years ago we were building 4 conventional submarines or 5.

Admiral RICKOVER. The fifth one of these conventional guided missile submarines was changed over to nuclear power. We are using a reactor for a 578 class and we are installing it in what started out as a conventional guided missile submarine at the Mare Island Naval Shipyard.

Senator JACKSON. The proposition was the Navy had asked for funds at a time when you had not commenced the trial runs for the *Nautilus*.

Admiral RICKOVER. Yes, sir.

Senator JACKSON. Subsequently, the trial runs took place but apparently someone failed, down in the Navy, to take cognizance of those results and so we had before the committee the fact that they were asking money for conventional submarines without having taken into consideration the results of the *Nautilus*. It was one of those unfortunate things. Admiral Carney was decent enough to admit it, but it was a lag that occurred and they did correct it to the extent of one.

Representative PRICE. I think the Navy has not asked for more.

Senator JACKSON. More conventional submarines?

Representative PRICE. That is right.

Admiral RICKOVER. You do have Admiral Burke over the barrel to this extent. Prices are going up 7 percent a year on everything. The Navy gets a certain amount of money for ship construction in accordance with the President's proposals, and the Bureau of the Budget. The nuclear-powered ships cost a lot, but he still has to meet today's problems and commitments.

I would strongly urge that for any development type ship there should be a separate budget. This would encourage the Navy to go ahead and try out new ships. As long as you attach costly development type ships to the one shipbuilding budget it poses an almost intolerable situation for the people responsible for running the Navy. It would not do any good to set up another budget but reduce the regular naval construction budget. That would not help. If something like a separate additional budget for the first of a development-type ship could be set up it would be a tremendous help in improving the Navy.

New type ships are very expensive, so if the Navy could be encouraged by having a separate budget for the first development ship of a type it would be a very tremendous thing. Because now Admiral Burke is spending for the nuclear-powered cruiser and for the nuclear submarines—and I imagine that is why there are only four submarines in fiscal 1958—he is spending quite a considerable portion of the shipbuilding funds on just a few ships, but he has many world commitments to meet, so what else can he do?

Representative PRICE. On your shipbuilding reactor program, are you just working on 1 type of reactor for each ship or do you have 1 or 2 or maybe more reactors that you are exploring for the various ships?

Admiral RICKOVER. For the submarines we are exploring different types, but for the surface ships, because of the large amount of development money involved, we are only working on two different types. That is for the aircraft carrier and the cruiser. Considering the many billions of dollars——

Representative PRICE. You mean 2 types for each ship or 1 type for the aircraft carrier and 1 type for the cruiser?

Admiral RICKOVER. It is immaterial whether it is for either one. We have a reactor a certain size.

Representative PRICE. They would fit in each ship?

Admiral RICKOVER. They would fit interchangeably. It would be wise from a national standpoint to be working on more than two types, considering the fact that we are going to be spending many millions of dollars on these ships.

Representative PRICE. Have you recommended we work on more than two types?

Admiral RICKOVER. I would like to recommend it. I would like to be encouraged by you to recommend it.

Representative DURHAM. That is the prototype land base you are speaking of?

Representative PRICE. If you think there is some question about the feasibility of it there might be a possibility of getting a more efficient reactor from one of them. I do not know why we should not explore it.

Admiral RICKOVER. You see, Mr. Price, we cannot ask for just any sum of money. We have to ask for something within reason. And I say, the Commission certainly has treated me very decently. But if I thought I could get more money, I would ask for more, because I know I can use it wisely.

Representative DURHAM. AEC furnishes all the money for prototypes for shore bases?

Admiral RICKOVER. Yes, sir; the AEC does that.

Representative DURHAM. Have you any new ones planned in the program?

Admiral RICKOVER. There will be one new one, but we have not asked for it yet. It has not gone far enough. It will be the frigate prototype. We expect to install it in the sphere at West Milton. We expect to ask for it in fiscal 1959.

Representative PRICE. Do you have in mind any particular type of reactor you would like to experiment with?

Admiral RICKOVER. Yes, sir; I would like to work on another type of reactor that would fit into a cruiser or an aircraft carrier. We are doing two different types now. I think it is important enough that we should do still another one.

Senator JACKSON. Mr. Chairman, I think it would be helpful, without going into it now, if we could get from the Admiral some indication of what additional funds he feels he needs. We requested it of him. It is not in the budget for fiscal 1958, under the request relating to reactors, research and development, and that whole area. If you could submit that to us at our request?

Admiral RICKOVER. I can give you a rough round figure. I could use $20 million. I could use in this fiscal year about $7 million or $8 million more. I could use a total of $20 million and get good use out of it.

Senator JACKSON. Just AEC funds?

Admiral RICKOVER. A combination of AEC and Navy funds. It would be roughly $10 million AEC and $10 million Navy. It is immaterial where the money comes from. I think you know we use some of it interchangeably. Your committee knows it and has approved of it.

Representative PRICE. How much do you need for this shipbuilding reactor program for one additional approach?

Admiral RICKOVER. It would take about $10 million.

Representative PRICE. About $10 million.

Admiral RICKOVER. About $10 million.

Representative VAN ZANDT. Have you the personnel?

Admiral RICKOVER. I can train additional personnel. That is a problem that comes up with any new program. If you have got to do something and you have an organization, you just go ahead and get more people and train them. No one doing a real job ever has any extra people.

Representative COLE. What are the two types you have now?

Admiral RICKOVER. We have two types which are good either for the aircraft carrier or the cruiser.

I will sketch it. You have in the center a part that is enriched uranium, and surrounding it is natural uranium. This is what we use on the PWR. In the PWR there are about 70 kilograms of U-235. The rest is natural uranium. The reason we have designed the core this way is because we are trying to use a minimum of enriched uranium in the large cores. We have to have enriched cores in the little reactors such as those for submarines, but for the larger ones we try to use as much natural uranium as possible, because to use enriched uranium entirely simply means running the natural uranium through a diffusion plant, and so burning up coal. There is not much sense to burning up a lot of coal, and then put it in a ship and use it for power, unless there is no other way to do it.

We are using the same principle of using as much natural uranium as possible, which can be used in one of the reactor cores which we are designing now, either in the aircraft carrier or the cruiser. We have designed it this way in order to have a minimum dependence on diffusion plants. We do not like to use too much enriched uranium because it is the same as burning up coal indirectly.

Representative COLE. Was it new?

Admiral RICKOVER. I do not know what it would be.

Representative COLE. I thought you had a concept.

Admiral RICKOVER. No, I would like to turn it over to the scientists working on it and have them come up with another type. I know I would like to design another one, but I do not yet know what it will be, sir.

Representative PRICE. I wonder if you could explain the different models so we know what we are looking at.

Admiral RICKOVER. Yes, sir. Let me first show you these charts. This is the control cubicle, the complete control for the propulsion plant of the submarine. This is where the operator controls the tur-

bines, and this is where he controls the reactor, and this is where he controls the electrical plant. This cubicle is very small. I think you are familiar with the large control stations you normally see around the various production plants. We have to get the control station very small. This shows you how small we can get it.

This chart shows the reactor which can be used either in the cruiser or in the aircraft carrier. This model of a man shows its actual size.

We have ordered the reactor pressure vessels both for the cruiser and the aircraft carrier. They have been ordered by competitive bidding. We have ordered the heat exchangers for both of those ships on competitive bidding, too.

This is a pretty good picture of what the aircraft carrier will look like. It has a 1,040-foot water line length, and almost 1,100-foot length flight desk. Her displacement will be about 86,000 tons.

Representative DURHAM. Could it get through the Panama Canal?

Admiral RICKOVER. No, sir. Nor can the other large carriers.

Representative VAN ZANDT. Is it possible to build a reactor into those ships with sufficient fuel to provide propulsion for the life of the ship, based on, say, 15 to 20 years.

Admiral RICKOVER. I would say this: with the type of operations we are doing now we sure should get about 5 years of operation.

Representative VAN ZANDT. Five years?

Admiral RICKOVER. Five today. But progress in reactor design is going so fast, sir. I think you could figure that ultimately you might get a reactor which will last the life of the ship. The goal we have now is to design a reactor which will last for a war. I think we have come pretty close to that. That is a great thing in itself because nuclear-powered ships will not need oil bases and oil storage tanks and oil tankers. Furthermore, you could store all the fuel you need for a nuclear navy in a few buildings. The fuel is not radioactive, and if you do not use it for the Navy you can always convert it to other uses.

This is the guided-missile cruiser. It is 690 feet long with a beam of 70 feet. This cruiser will be built at Quincy, Mass. It will displace about 14,000 tons.

This picture shows a preliminary design of a nuclear powered destroyer. We already have the nuclear propulsion plant in an early stage of design. The Knolls Atomic Power Laboratory is designing the reactor.

To show some of the models I have brought, this is a cross section of the core in the 578 class submarine. This is one of the fuel elements, and these crosses are the control rods.

This model is the machinery space of the 578 class, and this is the reactor plant.

We have two different types of reactor compartments for these plants. We have one where we use a tunnel type shield, that is, we spread the machinery out, and we use the B–29 tunnel concept of just shielding the passageway where the people walk through. The other type uses a regular shield deck like in the *Nautilus* where everything is under the shield. We are trying out both of these. We are building two ships of each type, and are going to try them out in service and see which is the better.

This is the *Albacore* hull type submarine. This is a cutaway of the pressure vessel and the core. The core is down here, and this is the

control-drive mechanism. You can get an idea of what the pressure vessel head looks like.

This is a model of the 578 class submarine.

This is another model of it.

This is a very interesting reactor.

This is the reactor which will go into the large radar picket submarine. It is a different type than the others. The others all use plates for fuel elements.

I have here a sample of a control-drive mechanism for the aircraft-carrier core. This one will be used at the carrier plant prototype at Arco. As you know, that prototype has two reactor cores.

Here is a sample of the control drive mechanism for the radar picket submarine. It is being designed by the United Shoe Machinery Corp., of Beverly, Mass.

Representative DURHAM. Is the shoeman in this business too?

Admiral RICKOVER. The United Shoe Machinery Corp. is pretty good in developing mechanisms. You see in the shoe business they have to use a lot of very complicated machinery. They are experienced in developing mechanisms. This gives you some idea of how we are spreading our development out.

Senator JACKSON. The Russians will have a terrible time trying to figure out what the American corporations are doing if they just read the stock lists and try to make a decision.

Admiral RICKOVER. That is right. We have companies such as Borg-Warner, Bendix, and Aerojet making controls. We have all kinds of companies in our business.

This model shows the pressurized water reactor. You will have to come closer to see it.

The scale of this PWR model is, I think, one-eighth. This is the core. This is the core loading and unloading mechanism.

I do not know if we brought one of the 600-pound bolts here or not.

Representative DURHAM. No.

Admiral RICKOVER. These bolts are 6 feet high and weigh 600 pounds, and secure the head to the pressure vessel. There are 43 of them. You can see that they are large items.

I wanted to talk a little bit about declassification before it is too late, because Dr. Libby has been involved in this. There has been a lot of criticism of the Commission for not putting out more information. So recently we declassified all naval reactor technology, but not the designs.

I would like to make a distinction between technology and design. I must make this clear so you do not misunderstand me. The experimental information which has been developed in the naval program is now unclassified and is available to all of our industry. But the actual details of the designs are confidential. That is, we do not give away design details.

The PWR is completely declassified and all the design details as well as the technology is now available to the public. We just started putting out all of the PWR reports on an unclassified basis. In naval reactors program all of the technology, all of the scientific and engineering information that anyone in this country needs to know to build a water-cooled reactor can be obtained. But we do not give away actual dimensions and design details except to those who need to know them.

There were two good reasons for doing it. One, as I see it, the Government is directly and indirectly subsidizing everybody anyway, so we might as well give them the information.

The other thing is it is getting too darn hard to operate with so many people coming into the laboratories and getting the information personally. We either had to spend much of our time and the time of the people in the laboratories handing out the information on a personal basis, or else do this through declassification. We decided it was better to take a little bit of a chance and so be able to get ahead with our own work. What we have done is, I think, rather significant. It will take some of the curse off the Commission and they will not be accused so much of not handing out information.

We have done another thing in the naval reactors program to make information public. We have put out a series of manuals on our program over the past few years.

We have published five manuals so far: The Liquid Metals Handbook, Metallurgy of Zirconium, the Metal Beryllium, Reactor Computer Codes, and the Reactor Shielding Design Manual. I have copies of these books here on the table. Another manual, Corrosion Handbook for Water-Cooled Reactors, should be published in about 2 months. There are five more on various technical subjects being written. They will all be published within about a year and a half. All of these manuals are completely unclassified. They are all real working books for people who have to do reactor design work. A man can use the shielding handbook, for example, and design a shield.

Representative HOLIFIELD. What is your evaluation of the philosophy behind making, let us say, all the shielding information or all the metal information like zirconium available? That immediately, of course, becomes available throughout the world. Do you think that gives us a disadvantage with our enemies?

Admiral RICKOVER. Certainly it does, sir. But this is the problem we are facing all the time: You get more of an advantage than you get a disadvantage. You get much more of an advantage because you get the information out to your own people. There is no use in subsidizing a lot of people to do work on zirconium in the United States and hinder them by not giving them the information which is available. But another serious thing——

Representative HOLIFIELD. In other words, the know-how, you are training them for a wider basis of participation.

Admiral RICKOVER. The information in the zirconium book does not tell you how to design a core. You have to get much more information to be able to do that. But it does have the complete story on how to make and use zirconium. I am not so sure other people are not just as smart as we are, anyway.

I think sometimes when you lock yourself up in a room and put the restricted data tag on it, I think perhaps you are kidding yourself more than you are other people. You can very soon get yourself in the position of thinking that you know it all, when you really do not.

These handbooks are put out commercially, by the way, and the publishing companies want to print them. By having these books available you get the people in the universities and in other places starting to think about the problem and making improvements. I do not think we could have gotten lower prices on zirconium if we had not made this information widespread.

Mind you, these books contain technology. We are not putting out actual design information on the dimensions of the shield for any of our ships. We do this for the PWR. That shield is concrete anyway.

Representative DURHAM. Was that not the first book published entirely on zirconium?

Admiral RICKOVER. There have been many papers published on zirconium, but this book is now the standard for zirconium all over the world, as far as I know. It certainly has all of the latest information in it.

It has another advantage. It was written by the people who are actually working with zirconium. Normally, text books are about 10 years out of date by the time they are published. But when it is done by the people who are actually working on it you have something right up to date.

Representative HOLIFIELD. In other words, the diffusion of this knowledge, you figure, among a wider base of potential engineers and scientists and so forth will give us the capacity for rapid advancement which you could get no other way.

Admiral RICKOVER. I will call on Dr. Libby to remind him of that famous day quite a few years ago when I appeared before his committee—he was at that time the chairman of the senior reviewer's committee—urging him to back us in putting out a Liquid Metals Handbook. That was about 1948, and it was the first time there had been any declassification in reactors. As a result of the Liquid Metals Handbook we got people in the universities and in other places to start working in this field.

You will find that today these are the standard books in the United States on this subject. There are no others. There are not any others with detailed scientific and engineering information in this field. So you have to make up your mind 1 of 2 ways. You are either going to keep the information locked up in Government or give it to industry and to the schools and so make it available to many people.

Sure you are giving information away. Is that not one of the strengths of a democracy, that we assume we can live in a democratic way and still stay alive? It does not mean that we must give away all the details of everything, but it does mean we must give away enough so that our own people can be aware of our problems and help us. You cannot give without taking chances.

Representative HOLIFIELD. It is the only way you can really widen the base in this shortage we have?

Admiral RICKOVER. I am not talking now, believe we, from a theoretical standpoint. We declassified information because we found out that our work was being hampered.

Representative VAN ZANDT. Admiral, are these books becoming part of the atomic library that the AEC is planning throughout the Nation?

Mr. RODDIS. Yes, sir.

Admiral RICKOVER. There are quite a few more coming out.

As I have said, six more are coming out in the near future. There is one every half year or so.

Representative DURHAM. Have you declassified the separation of hafnium from zirconium?

Admiral RICKOVER. Yes, sir.

Representative DURHAM. When did you do that?

Admiral RICKOVER. I think in the last 2 or 3 months. We will include this information in the Hafnium Handbook which is now being prepared. We found out the Russians know about hafnium anyway.

One other thing I believe I should tell you is how we run our projects. We operate the Naval reactors program in somewhat of a different way than other programs are operated.

There are two theories for running reactor programs. One is to assign it to a contractor and give him the money and let him run the job all by himself. The other way is to retain control at a headquarters organization.

When you have to design and build a reactor for a ship you cannot turn it over to somebody else because it has to be integrated right into the ship. For instance, a submarine has to have neutral buoyancy. You cannot leave it up to a contractor to start designing the reactor, and a year after the ship is started you suddenly find out that the reactor weighs too much. The ship will sink.

So our philosophy has been from the beginning, and we have used it on the PWR also, that the Naval Reactors Branch approves the details of the design. We keep in constant touch with what the reactor designers, the machinery designers, the shipbuilders, and the construction contractors are doing.

We have in my organization at headquarters about 90 officers and civilians. They constitute the headquarters engineering and administrative staff.

These people work both for the Atomic Energy Commission and the Navy interchangeably. There are officers and there are civilians, and I think you all know that I assign people to positions on the basis of ability and not rank, or whether he is a civilian or an officer. The best qualified man gets the job.

We operated this way for a long time, and it is now accepted. In my opinion it is the only way you can run any kind of technical organization; put the best people in the most important jobs.

Senator JACKSON. Would you explain the two hats I think you wear at some point?

Admiral RICKOVER. Yes, sir. My primary duty is on assignment to the Atomic Energy Commission. I am Chief of the Naval Reactors Branch of the Atomic Energy Commission. So I act for them with the AEC laboratories and other activities. I have an additional duty as Assistant Chief of the Bureau of Ships for Nuclear Propulsion. That means that anything that has to do with the nuclear-populsion plant for the first vessel of a type comes under my cognizance. Of course, I am responsible to the Director of Reactor Development in the Atomic Energy Commission and to the Chief of the Bureau of Ships in the Navy Department.

Senator JACKSON. Is this two-hat system working?

Admiral RICKOVER. Yes, sir. I would advise anyone who has a large-scale development job to do to adopt 2 hats or 3, whatever number is necessary. It is a new experiment in development administration. We have never had anything quite like this. We have always had liaison among bureaus and between one Government agency and another. But here there is one group of people working for both a civilian agency and a military agency. It is sometimes a little diffi-

cult, but it works, and it works particularly because the AEC people have sure stood for a lot from us—I don't know why, but they do—and they deserve a great deal of credit for their forbearance and their help. In my opinion, this type of Government operation is absolutely essential in the future for any large-scale development operation. If you do not have it this way you get fouled up with lots of redtape.

Representative VAN ZANDT. Is there any effort afoot to dissolve this unique organization you have?

Admiral RICKOVER. I do not know. I would imagine there are people in some places that are not too happy with it, but I certainly hope, whether it is me who is involved, or someone else, that this organization not only is not dissolved, but I would strongly urge that people in Congress should eye this method as a new form of Government research and development administration. I think it is absolutely essential that the military no longer attempt to fight wars all by themselves, or do large-scale research and development all by themselves.

My organization is really more than a two-hat one, sir, because it includes more than the AEC and the Navy. Actually there is a third hat—industry. I think some of you know how closely we work with industry. We have gotten a real integration of industry, the Navy, and the AEC on this job. There is no other way we can do it.

Representative PRICE. We are getting close to that point at least. Could you explain your Branch? The Naval Branch of the AEC is set up to carry on the Shippingport project?

Admiral RICKOVER. Yes, sir. The PWR Shippingport project was assigned to me by the Commission because of the previous experience that my group had had with pressurized-water reactors. The Westinghouse Co.'s Bettis plant was assigned to do the necessary development work. The development work is now almost finished for the first core. The Duquesne Light Co. was selected from among nine contenders to be the operator of the entire plant because they made the best financial offer to the Commission. But my organization is responsible to the Commission for the design, the construction, and the operation, and we spend a great deal of time on it.

The Bettis plant submits the nuclear-plant designs to us and we analyze them and reach joint agreement. In many cases the Duquesne Light Co. is also involved in nuclear problems, because they are going to operate the plant. We are able in this way to reach quick decisions between the Government, Westinghouse, and Duquesne.

We are able to operate this way because there is a single, assigned responsibility. Otherwise, we would all be writing letters from now to doomsday, between the Commission and somebody else, to get permission to do anything. We are able to do our work with few letters and no fuss. There has never been a single letter written between the Commission and the Duquesne Light Co. since the contract was signed with them. It has never been necessary, because all of the dealings have been done orally between myself and their manager or Mr. Philip Fleger, their chairman of the board.

Representative PRICE. You mentioned a minute ago you had about 90 people in your headquarters organization. Is that strictly for the ship-reactor program?

Admiral RICKOVER. No, sir; that includes people who work on the Shippingport reactor. But, besides these people, we use somewhere

between 150 and 200 people in the Bureau of Ships to work with us not only on the naval program, but also to help on the Shippingport project. It makes no difference what Government people do the work, because the money all comes from the same source. The Navy is glad to help, because we are not only helping the Commission and the country, but we are also learning a great deal for the naval program by doing so.

We try as far as possible not to duplicate facilities between the Navy and the AEC. For example, when we buy nuclear cores on competitive bidding for the Navy, for which the Navy pays, we do it through the AEC. If we did not do it through the AEC, we would have to set up a separate organization to account for the fissionable material, and to prepare the specifications, to inspect the cores, and to take care of other items.

So far, we have been permitted to use the Atomic Energy Commission facilities for this purpose. I strongly urge that, wherever we can, regardless if the core is for a naval reactor, as long as the AEC has the people and facilities for doing so we should use them, and not set up additional, duplicate, Government organizations. It is not only wasteful of manpower and money, but every additional organization you set up saps your strength and does not give you time to do your technical work. You get completely bogged down with administration and redtape.

Representative PRICE. Have you moved this Shippingport organization over to some other project intact, or what will you do with that?

Admiral RICKOVER. We are working on a new core design for the PWR reactor. The present core is designed for 60,000 kilowatts of power. The Commission authorized us about a half year ago to work on a new core which will be of an improved design. The new core is being designed to generate 100,000 kilowatts of power and to produce this power more cheaply than the first core. We have already started the new core design for the PWR reactor.

Representative PRICE. How close do you come to keeping any sort of schedule on the Shippingport project?

Admiral RICKOVER. We have not come close to keeping on schedule.

(There was discussion off the record.)

Representative PRICE. I saw where you got considerable publicity on a speech you made recently about the engineering and technical problems encountered in the atomic-power program. In view of your experience with PWR and Shippingport and other facilities, do you think we have a realistic schedule now on our current atomic power development program?

Admiral RICKOVER. From my experience so far, I would say that all reactors are going to cost considerably more and take considerably more time to design and construct than was originally anticipated. I am, of course, talking from my own experience, but certainly we are pushing our programs hard and still running into many delays, so I would think other people are going to experience the same thing. As you know, the costs at Shippingport have gone up.

Representative HOLIFIELD. How much have they gone up?

Admiral RICKOVER. Congress originally authorized the Shippingport project for a total of $100 million. We estimated then it would cost $85 million. The latest cost estimate as of today is about $42 million for research and development and $55 million for construction

of the nuclear portion of the plant. Of this $55 million, $5 million was given to the Government by the Duquesne Light Co. as part of the contract we made with them when they were selected. So the Government cost is $50 million for construction plus $42 million for research and development, which makes a total of about $92 million. That will be the cost provided we can finish it in a reasonable time. If the time is stretched out, the cost will go up.

(Discussion off the record.)

Admiral RICKOVER. The costs of all reactors are going up, sir. I would estimate from what I have seen you can expect probably at least a 50 percent increase in all of the large reactor projects. I am talking from my own experience. This is what my experience indicates.

(Discussion off the record.)

Representative PRICE. Admiral, going back to your experience at Shippingport now, do you think your trained force, experienced people, with the experiences they obtain and develop at Shippingport and other jobs in your program, could take on the job of building a large-sized, gas-cooled reactor to supplement the present power program?

Admiral RICKOVER. Mr. Price, you know I am not responsible for civilian reactors.

Representative PRICE. I know you are not. I am just asking, do you think your people, at least from Shippingport experience, would be interested in such a project and kind of like to undertake such a project?

Admiral RICKOVER. If it were assigned to us we would take it. That is up to the Commission.

Representative PRICE. Would you like to do it?

Admiral RICKOVER. Sure, I would like to do it because most of the people in my program are not in it for the naval program alone. They are interested in helping to bring atomic power to our country, because they believe atomic power is necessary for our future welfare. The Navy is helping to bring atomic power to our country because whatever we develop or learn in the naval program is of use in civilian reactors.

Representative PRICE. Do you think your group is in pretty good shape to take on an assignment like that?

Admiral RICKOVER. No, sir, we are not, but we could put ourselves in shape.

Representative VAN ZANDT. Projecting our thinking into the future, Admiral, when your reactors are standardized as far as ship propulsion is concerned, would it then be necessary for this unique organization you head to continue?

Admiral RICKOVER. For quite some time, yes, sir; because the whole reactor game hangs on a much more slender thread than most people are aware. There are a lot of things that can go wrong and it requires eternal vigilance. All we have to have is one good accident in the United States and it might set the whole game back for a generation. We do not want that to happen.

It requires a high order of ability and intelligence among the engineers and a high order of watchfulness to insure that nothing goes wrong.

Representative PRICE. Let us get back for a minute to the point I raised in regard to your recent speech about a realistic schedule in our power program. Do you think the target dates for around 1960 and 1962 are realistic?

Admiral RICKOVER. For what, sir?

Representative PRICE. For a large-scale operation of power reactors.

Admiral RICKOVER. To have a considerable number of power reactors in the United States?

Representative PRICE. Yes.

Admiral RICKOVER. No, sir.

Representative PRICE. What do you think would be a realistic target date?

Admiral RICKOVER. You are really getting me out of my field and I think you have people here far more expert on that than I am.

Representative PRICE. I am asking your personal opinion. You have had quite a bit of experience in the reactor building program and are not entirely unfamiliar with the power program.

Admiral RICKOVER. I think some of the people working on the program are not entirely realistic, they are not facing up to the facts of life. I do not think they have had enough practical experience. I do not think they worry enough.

You see, when we design reactors we have to think of putting them into a ship, and I have one design criteria. I always ask myself, would I want my son to go in the ship? If I can answer that question affirmatively, I say it is all right.

Representative PRICE. When you say they are not considering all problems, what would you mean by that?

Admiral RICKOVER. For instance, some of these reactor designs, as I see them, do not take into account some of the things that might go wrong, so they do not put into the design enough features, in my opinion, which would take care of them.

Representative PRICE. In other words, you do not feel the reactor is a proven thing until you know what it would do in event of an accident.

Admiral RICKOVER. That is why we build prototypes and try them out.

Representative PRICE. What do you think—I am just trying to think of an example of what you are talking about there. Would you say EBWR at Argonne, for instance, is a proven thing until you have something go wrong there?

Admiral RICKOVER. No. As far as I am concerned, all EBWR has so far proved is that if you get enough uranium together you have a critical mass. I think Argonne has done a fine job in designing and getting the EBWR in operation so fast. They are learning from it a great deal about control and operation of boiling water reactors. But until they fully try it out and, deliberately perhaps, have a ruptured fuel element go into the system and see what happens, I do not think they have finally proven the reactor system.

Representative PRICE. They have never done it?

Admiral RICKOVER. I think probably they will do it.

Representative PRICE. They have not done it yet?

Admiral RICKOVER. As far as I know, not.

Representative PRICE. Of course not with the new reactor, but with any similar type reactor have they done it?

Admiral RICKOVER. In my opinion, I see no point in conducting experiments of that kind unless you finally go to the bitter end and see what happens if you do have a burst fuel element. Only then will you know whether you will be able to operate the plant or not.

Representative DURHAM. Did they not test the one prior to Argonne?

Admiral RICKOVER. As far as I know they are planning to do this, but as far as I know—probably Commander Roddis knows better than I do.

Representative DURHAM. Was not the original borax tested, Doctor, originally?

Mr. RODDIS. There have been three experiments of boiling water reactors conducted: Borax 1, 2, and 3. One of them, borax 1, carried to destruction. Borax 2, during its operation and later borax 3, during its operation, have operated with aluminum fuel elements, which have received pittings, according to previous information. The type fuel element being used in the EBWR is a different type of fuel element which is much more susceptible to corrosion than the borax reactors.

Admiral RICKOVER. What I was saying was this: Until there is a burst fuel element and it gets into the system and you see whether you can operate the plant the experiment is not finished. That, to me, is the most important part of the experimental program on a reactor of that type. I am sure they will do it.

Representative HOLIFIELD. Let me try to follow you on this. Have you done that in the prototype of the PWR reactor?

Admiral RICKOVER. You see the PWR reactor has heat exchangers so that the water which goes through the reactor is kept separate from the steam system. But in a boiling water reactor the steam goes directly from the reactor to the turbine. We deliberately burst a fuel element in our submarine prototype plant at Arco and because of the heat exchangers in the system we were able to keep on operating.

Representative PRICE. That is what we are trying to find out, what you meant by that.

Admiral RICKOVER. These are the things you have to take into account in a naval plant. We have to postulate that these things will happen. So that even with a burst fuel element at Arco we were able to live with it. We have also had more than 100 gallons leakage of water per hour but we found we can live with it.

A lot of complication in our designs is due to the fact that we go to great expense and trouble to visualize these sorts of situations and in designing for them. This is what makes our plants complicated and expensive.

Representative PRICE. What sort of management controls do you use?

Admiral RICKOVER. I receive once a week a series of critical items lists from each of our projects. These are the items that are in design trouble, or need help, or where there is delay or there is something wrong. We give immediate attention to these problems.

Representative VAN ZANDT. You write no letters?

Admiral RICKOVER. We do write letters especially on technical matters, but a great deal of our work, particularly on expediting development and manufacture, is done by telephone. We do not wait, We get after this kind of stuff right away.

We also receive technical progress reports regularly from our contractors, and we comment on them. If you will look at these [indicating] you will see the type of reports we get on each project. We try to get the reports in 10 days after the end of the month or whatever the reporting period is, and we comment on it and tell the contractors and laboratories what we do not agree with. We do a lot of this sort of work all the way through each project.

Representative PRICE. How many people are there in the naval program?

Admiral RICKOVER. We have at Bettis about 1,300 scientists and engineers. These take care of the PWR project also. At the Knolls Atomic Power Laboratory, about 500; at combustion engineering, about 200; which makes a total of 2,000. At the laboratories and factories of our subcontractors there are probably an additional 1,000 scientists and engineers. Therefore, there are about 3,000 scientists and engineers working in the naval program plus the PWR.

On a project like the PWR it takes about 250 scientists and engineers, plus another 750 people, 5 years, roughly, to do the development work. That is pretty much the number of people and the time required for the research and development of any of these large projects.

These are fairly well trained people, not people you hire right now or pick off the street. A good many of them have come from the parent organization and have not been newly hired from outside.

Representative HOLIFIELD. In other words, some group that starts to build one of these large-size reactors without this organization——

Admiral RICKOVER. They will take several years to really learn.

Representative HOLIFIELD. Several years to perfect their organization to the point where you have it now, is that right?

Admiral RICKOVER. Yes, sir. It took us quite a few years to do it. My organization has been in the process of being formed for quite a few years. We are constantly training people. Every engineer or scientist I hire goes through a special selection system, the officers as well as the civilians, and we give each one of them special courses of training in the reactor field. Every engineer in my office has been given specialized education.

Representative PRICE. You give them training on the projects?

Admiral RICKOVER. Training at schools too.

Representative PRICE. What type of schools?

Admiral RICKOVER. The Oak Ridge School of Reactor Technology, Massachusetts Institute of Technology. We have schools at Bettis also. The school there lasts about 6 months. Every one of our engineers, officer or civilian, must attend one of these schools.

The young officers we get must agree to stay for 4 years before they can come into my organization, and many of them stay on as civilian engineers after their naval time is up. They stay with us because the work is interesting and they are able to do as much as they are capable of—to fulfill themselves. You have got to train people if you want to keep them.

Representative DURHAM. You have regular Navy personnel working for you, do you not?

Admiral RICKOVER. Yes, sir; I have Naval Reserve, regular Navy, and civilians.

Representative DURHAM. How about the pay schedule? Ordinary civilians, say as a civilian engineers, do they complain about the difference in pay?

Admiral RICKOVER. No, they do not. The officers are really discriminated against in this situation. We have fairly young civilians working right alongside officers with a good many years of service, and the civilians get more pay.

I hope that the Cordiner report, or some similar measure is placed into effect to take care of the outstanding and motivated officers in my organization. Although our people are not working entirely for money, nevertheless nearly everyone in my office could get a job at a much higher salary. We have a very low level of departures.

Representative DURHAM. Have many left you?

Admiral RICKOVER. No.

Representative DURHAM. Naval personnel, I am talking about.

Admiral RICKOVER. We have had more naval personnel leave than civilians, but our rate of attrition is not high.

Representative VAN ZANDT. Is it a change of assignment or do they resign?

Admiral RICKOVER. The officers who have left, generally get out of the Navy. They say they are not making enough money to support their families properly, and there are many opportunities in industry at much higher pay for people who are as qualified in this field as they are.

But most of them, not all, who have left have not been the most outstanding. Commander Roddis, however, was one of our outstanding people.

Mr. RODDIS. I did not leave for money though.

Admiral RICKOVER. No. But some who have left—we have not cared very much whether they left or not. In general, our good officers stay around, and I think you can get people to become dedicated to a job where they feel they are doing something constructive and worthwhile—they learn that money is not everything in life. And, of course, it is not. There is also personal fulfillment when you are doing the kind of job you like to do, and that is really the important thing.

Representative PRICE. What kind of action do you get out of AEC area offices on contract expediting?

Admiral RICKOVER. The AEC area offices do a good job for us. The whole AEC does a good job for us. It is a very fine organization. As I said before, without the AEC we would not now be on the way to a nuclear-powered Navy.

Representative PRICE. In many of your cases, do the area offices handle the contracts?

Admiral RICKOVER. Yes, sir. I do not know what the figure is. Up to a certain amount they can be handled locally in the local AEC offices, and anything over about $2 million has to come into Washington.

Mr. RODDIS. It varies with different offices. Mr. Flaherty at Argonne has authority to make contracts for $5 million.

Admiral RICKOVER. I would like again to state Admiral Holloway—our Chief of Naval Personnel—has done an outstanding job in taking care of our needs. He has helped us tremendously.

Representative VAN ZANDT. Some years ago we were concerned about the possible thievery, we will say, of trained personnel from your organization when authority was granted to establish, we will say, the shipbuilding capabilities in this atomic field. Has that actually taken place?

Admiral RICKOVER. You mean, has there been any trouble with pirating of people trained in the nuclear field in the shipbuilding organizations?

Representative VAN ZANDT. That is right.

Admiral RICKOVER. There has not been much, sir. You see, whenever a new shipbuilder gets into this game we know it ahead of time and we train his people; we arrange for his people to go to school. We also send people from my organization to deliver lectures and to advise them on training. We have set up, not only for shipbuilders but for every industrial outfit that comes into our game, a system of training.

Let us take metals and controls, as an example. We sent people there to deliver lectures, and we arranged for their people to go to schools. This is part of the regular course of training.

It so happens that Captain Dunford is responsible for that phase of our work in my office. We make sure that all of the industrial companies that work for us are trained. We cannot just let them do this by themselves because they do not know how to go at it. And that applies to the shipbuilding companies, too.

Representative VAN ZANDT. Is Ingalls down in the gulf developing capabilities to build submarines—atomic submarines?

Admiral RICKOVER. Yes, sir.

Representative VAN ZANDT. How long is it going to take them to assemble trained personnel?

Admiral RICKOVER. They started 2 years ago. Two years ago, when it was decided they would enter the submarine field, we started training their people. Now they have a number of people who are qualified. But it will take much more training. It takes several years. The Newport News Shipbuilding & Dry Dock Co. and the Bethlehem Steel Co.'s shipbuilding division at Quincy, Mass., have been training their people for several years in the nuclear field. We have helped them. They are still giving special training to their people. It takes several years to train a shipbuilding organization to become reasonably competent to build nuclear-powered ships. They must change some of their previous methods. It takes higher skilled people than you usually have in the shipbuilding industry.

For a company to get ahead in this game at the present time they must assign their best people and the man in charge must be of top-management caliber. The companies have done this. They needed some urging, of course, but once their managements finally saw the nature of the problem, they did what was necessary. We have had trouble, but we have been able to obtain cooperation. Perhaps you were referring to the Committee on Education that you and Mr. Price were on last year.

I said at the time I thought there were too many people just crying and wringing their hands and waiting for somebody to come along

and help them. In many cases they themselves can do much. Anyone responsible for a reactor project must take on the problem of seeing that his contractors and subcontractors hire the right sort of people and then trains them. Unless he does this he is in for trouble.

Representative VAN ZANDT. Then all of this excitement kicked up here a year or so ago about raiding your organization actually did not materialize, did it?

Admiral RICKOVER. No. No one is raiding my organization. Any one in my organization who wants to leave, I would just as soon have him out of it.

Representative PRICE. Are there any questions?

Thank you very much, Admiral, for a very fine presentation.

Representative VAN ZANDT. It was well done.

Senator JACKSON. I think he is to be commended always. We get forthright answers and he has done a good job.

Representative PRICE. The committee has always had fine relations with Admiral Rickover.

Admiral RICKOVER. You know how I enjoy coming up here. I know that you are all my friends and I sincerely thank you. I know you will do anything you can to help me in this program.

Representative PRICE. Thank you very much for your testimony this afternoon. It was very interesting and helpful.

(Whereupon, at 4:05 p. m., the hearing was concluded.)

PROGRESS REPORT ON NAVAL REACTOR PROGRAM AND SHIPPINGPORT PROJECT

FRIDAY, APRIL 12, 1957

SUBCOMMITTEE ON RESEARCH AND DEVELOPMENT,
JOINT COMMITTEE ON ATOMIC ENERGY,
CONGRESS OF THE UNITED STATES,
Washington, D. C.

The Subcommittee on Research and Development met, pursuant to call, at 10:30 a. m., in the conference room No. 1, Westinghouse Bettis plant, Pittsburgh, Pa. Hon. Melvin Price (chairman of the subcommittee) presiding.

Present were: Representatives Carl T. Durham (chairman of the full committee), Chet Holifield, and Melvin Price.

Staff members present: James T. Ramey, executive director, and George E. Brown, Jr.

Representatives of the Atomic Energy Commission: Kenneth E. Fields, General Manager; W. Kenneth Davis, Director, Division of Reactor Development; Rear Adm. H. G. Rickover, Chief, Naval Reactors Branch, and Commander V. A. Lascara, Naval Reactors Branch, John M. Bodley, special assistant to Commissioners Libby and Vance; Bryan F. LaPlante, congressional liaison officer; L. D. Geiger, Manager, Pittsburgh Area Office and Comdr. R. V. Laney, assistant to Pittsburgh area Manager (reactors).

Representatives of Westinghouse Electric Corp.; Charles Weaver, vice president in charge of atomic energy; John Simpson, manager, Bettis plant; Dr. Sidney Krasik, manager, central physics department; Dr. Benjamin Lustman, manager of metallurgy department; Mr. Alexander Squire, manager, submarine fleet reactor; and Dr. Walter Esselman, manager, advanced development group.

Representative PRICE. The meeting will come to order.

The Research and Development Subcommittee of the Joint Committee on Atomic Energy is here at the Bettis plant today in connection with its continuing studies in the atomic energy program. The joint committee is empowered to hold hearings at such times and places as it chooses and this meeting today is in keeping with the committee's tradition of visiting key installations as frequently as possible. First of all, I would like to commend the Government and private employees of Bettis. Your achievements in developing the *Nautilus* is of worldwide fame and I am sure my colleagues on the committee share my confidence that your work ahead will bring forth equally successful projects. I understand that Admiral Rickover will introduce this morning's speakers.

Will you proceed, Admiral Rickover?

STATEMENT OF ADM. H. G. RICKOVER, CHIEF, NAVAL REACTORS BRANCH, ATOMIC ENERGY COMMISSION

Admiral RICKOVER. First I would like to express for the Commission and for Bettis our appreciation of the opportunity to have you people here. We appreciate it a great deal and I am sure that by getting a firsthand look at some of the things that are going on here you will have a better understanding of what it takes to build a reactor plant.

Representative PRICE. Before you proceed, I would like to call to the attention of the gentlemen who are present here that while this is a subcommittee group here this morning, we are honored with the presence of the chairman of the full committee, Mr. Durham.

Admiral RICKOVER. It is a coincidence, but yesterday the *Nautilus* went to sea with her new core. Her core was successfully installed and she is at sea again. We have both the *Nautilus* and the *Sea Wolf* at sea. The *Sea Wolf* is at sea for about a month. She left early this week. However, the *Nautilus* refueling job is completed and the new core will give her significantly greater cruising radius. As you know, this new core was also designed by the Bettis Laboratory.

Since this meeting is intended to show what the Westinghouse Co. has done with the Bettis Laboratory, I will stop and introduce Mr. Simpson who is the general manager here. I think I should also introduce Mr. Weaver who heads up the nuclear work for Westinghouse and who was the first manager here. Mr. Simpson will take over.

Representative PRICE. Mr. Simpson, before you start I would like the record to show also that the General Manager of the Atomic Energy Commission, Mr. Fields, and the Director of the Reactor Division, Dr. Davis, are also present at this meeting.

STATEMENT OF JOHN SIMPSON, MANAGER, BETTIS PLANT, WESTINGHOUSE ELECTRIC CORP.

Mr. SIMPSON. Mr. Chairman and gentlemen, my purpose today is to try to tell you a little of what we at Bettis do; how we go about the work of the research and development and design of reactor powerplants.

As you know, Bettis was started about 8 years ago in order to do the work necessary to build the prototype of the *Nautilus*. We are very proud of the fact that the Bettis plant was started by Westinghouse taking largely people from other Westinghouse locations in an attempt to start the laboratory without taking people from other existing atomic-energy installations; that is to create a new factor in the atomic-energy field and not merely transfer existing technical manpower. We were quite successful in that and even today the average service with Westinghouse of the 400 supervisors at Bettis is more than 8 years. In the early days approximately 80 percent of all the supervisors, both technical and administrative, came from other Westinghouse locations.

At Bettis we do the engineering job on reactor powerplants, but in addition to that we do the necessary research and development that is essential for the engineering of those reactors. The reactors that we

have been working on in conjunction with the Naval Reactors Branch and the Pittsburgh area office of the Atomic Energy Commission for the latest submarines and the surface vessels have all been pressurized water reactors, but they are far different from the reactor that powered the *Nautilus*. There has been and there still is much research and development needed within the scope of the pressurized water reactor. It is a big development job.

As an illustration of the development required in the building of a reactor I would like to use the reactor core itself. In the reactor core we bring to focus physics, metallurgy, and straight engineering in the mechanical design sense of mechanical and thermal design. There is a big interrelation between the physics and metallurgy in the reactor design which requires an unusually close cooperation—a step-by-step development process—either one of which being adverse sufficiently can eliminate the material from consideration. So it is a typical problem to keep the two in balance.

Along this line it is relatively simple to determine, for example, that a new material appears to have great promise in a reactor; uranium-niobium, for example, or uranium oxide. In a few days a few metallurgists and physicists together can come up with the feasibility of such a material, but then there is an order of magnitude of tens to hundreds of times more work before you get to the point where you can actually use that material in a reactor. Uranium oxide, because it is an oxide, does not—it cannot further oxidize and it would be noncorrosive and inert in water. You can know in general what its physics properties are, but in order to really use it, many months and even years of development are required in the physics to understand how it is used.

In physics our reactor program has been limited in the past and still is to some extent by the lack of knowledge of the basic physics concepts. For example, until recently, there was difficulty in knowing exactly what the yield from fission was in the way of xenon. While this is not very important if you are just designing reactors in general, when you are getting down to the brass tacks of a particular design that must work, that and other similar constants, to a high degree of accuracy, become quite important.

The next area in which we must do a lot of work is taking the various assemblies of uranium of various enrichments and various geometrical configurations in determining the basic reactor. Having gotten through that, which usually requires a critical experiment which is an expensive and time-consuming thing, and which takes a great deal of technical manpower, we design the reactor.

Then in the design we must know other things than the basic parameters of the reactor. We must know exactly what is the distribution of neutrons in the reactor because that determines how the heat is produced and you must cool it properly in relation to the way the heat is produced, or you produce a hotspot and this may cause the reactor to melt down. You must know to a relatively high degree of precision the distribution of the flux.

Today's technology does not permit calculation on analytical techniques. This must be determined by experiment. We must determine how many control rods to use. We must determine whether or not the reactor will, in fact, be critical even with some of the rods not

all the way in, to be sure that it is safe. These things can be determined from a critical experiment run in a laboratory. A certain amount of the dynamic action of a reactor can also be determined by laboratory experiments.

Then you get into the more difficult things in which we must have a good basic theory in order to extrapolate, and the most important of these is the lifetime behavior. As you know, a power reactor must last for many thousands of hours. Uranium is burned and plutonium is formed. These are the fissionable materials and, therefore, the net reaction varies with time. You must determine and predict in advance what the control situation will be and what the flux distribution will be even after many thousands of hours of operation. This we cannot do by experiment in a laboratory because, in fact, it depends upon running the experiment at power for long periods of time. This information is verified from data we get from such reactors as those at Idaho, from the naval reactor facility, from the *Nautilus*, and which we expect to get from the Shippingport reactor. But in order to calculate these to the degree of accuracy required, we must have a firm foundation in the experiments we can make, which are with the cold reactor in this nude condition.

Moving on to the materials aspect, with each new reactor there is usually a new requirement for a material that will best fill the needs of that reactor type. This means a large metallurgical program in the development of the materials. By the development of materials, I mean developing a material that is adequately corrosion resistant, that is irradiation resistant and, in determining its physical properties, whether it can be machined, its strength, its ductility, and its other physical properties that you must know how to fabricate. Now this is not an easy job. In times past, as you know, a new alloy has taken 5, 10, or more years from its inception to where it is really reduced to practice.

It is a relatively easy thing—and I repeat this—it is a relatively easy thing to believe that an alloy with a given number of constituents would really be a useful and good alloy in a reactor, but to actually prove this—to develop all the knowledge of what impurities cause it to corrode, just how it works best, its corrosion resistance in pile and its irradiation resistance—it is a big and laborious job.

Then, having gotten the material, one must learn how to fabricate it. Fabrication is a difficult thing because there you must learn to weld. You must learn what the shrinkage and distortion is. You must learn all the many problems of rolling and fabricating so that you can, in fact, make a reliable core to be used in the reactor. We must go into the material itself from the pilot stage, where you make a small ingot, on to the production stage where many suppliers make large ingots.

Recently in something that we know almost the most about, which is the zirconium alloy—zircaloy 2, we found that when we went to large-scale production that the difference brought about by large-scale supplier production as against laboratory production produced certain inharmonies; lack of uniformity of material and this, in turn, affected its corrosion resistance. Some variations in the process had been instituted and these interfered with its purpose as a corrosion resistant alloy.

Another area in which a lot of work is done and a lot of work is needed is in the area of heat transfer and fluid flow. I think many

people had believed that water being such a common substance surely almost everything was known about its heat transfer properties, about its flow resistance in pipes even with a little steam present, but the facts are that very little is known about this. More is being learned each year, but still the data is not as good as is needed for the design of a reactor.

In addition to the development work on the core, as represented by the heat transfer, the mechanical, the metallurgical, and the physics, the rest of the plant is a big development job because essentially none of the components that we can put into a reactor plant today can be taken off the shelf. They, themselves, have many developmental aspects.

Aside from the development aspects of the components, we have the big design engineering job of coordinating all of this equipment into one powerplant to produce power—electricity or a shaft turning. Why is that so complex a job? The jobs are not larger in physical size than many other jobs that are done in the United States. I think the biggest reasons are the newness and the uniqueness of the components and the close interrelation of all these components. A reactor powerplant is closely coupled in several unique ways. The core emanates radiation and, therefore, you must shield the entire plant. This is, of course, a larger job on a submarine or a naval vessel than it is in a land powerplant because you must tie everything together in interrelating the shielding, the hull, the weight and space, and you must know what effect the components have in filtering out some of the radiation. The job must be done as a whole. You can't do parts of it and then just casually fit them together. The job must be engineered from the ground up with the entire scope of the project in mind.

Then you have the radiation heating of all the material that you use to support the core. These materials absorb gamma rays and this introduces design complications. Then in a pressurized water plant large sections of pipe are under high pressure. The whole plant acts as one unit from a thermal expansion viewpoint and you must arrange to take up this expansion, otherwise you will cause a break in the pipe and release of the fluid. Then you have the problem of radioactive contamination. The corrosion products that go through the core have radioactivity introduced into them and they go through the pumps, the pipes and the valves and you must be prepared to handle the maintenance of the plant despite the fact that you have some radioactive contamination.

Then there is that close coupling of a reaction upon the power of the reactor due to the pressure and temperature of the water. Opening a valve some place—starting a pump—can change the temperature of the water going through the core and therefore change the power. So your control must be such that those things don't happen except in the way that you predict and your overall control must be better due to the close coupling and reflection back on the core itself of all of the parts of the plant.

A reactor plant must have all of its components working in order to run. You cannot run a reactor powerplant with parts of it not working. The control drive mechanism, the instrumentation, the pumps, the valves, the heat exchangers—they must all work. This

93263—57——7

means that in order to get the maximum amount of information out of a plant like Shippingport you must keep it running in order to find out what you need from the core.

In building a reactor for a naval vessel we are not building experimental reactors. We are building reactors that must power the fighting vessels of the Navy. These reactor powerplants then are built so that they are rugged, reliable, and easily maintainable. They must work in fact. A submarine powerplant cannot shut down when it is on a battle mission or even when it is cruising simply because something doesn't work. You must have it so that these things do not happen.

In order to accomplish this, it has been necessary to what might appear at a casual glance to overdesign, to overtest—in order to give what we think of as maximum assurance that all of the parts individually will work and that they will work as a unit when coupled together. We have had to do a great deal of testing of components, and then test groups of components, and then overall testing of the plant. This we feel is a very important part, made doubly so, as I said, because these components that go to make up the plant are not ones that you can buy—that have been used for years and that have a long history of satisfactory operation.

For example, canned motor pumps were developed in the sizes used for the *Nautilus* and, therefore, in order to make sure that these pumps were satisfactory, a great deal of development and testing was required. The same is true of our heat exchangers, valves, particularly pressure relief valves and the pressure vessel itself which seems like a relatively simple item—just a heavy-walled vessel with a head on it—but the head required a tremendous amount of development so that it could, in fact, be built with a large number of holes in it for the control drive mechanisms and other purposes.

I have gone through the broad picture of the development problems in physics, in metallurgy, and in powerplants. I would like to call on some of my colleagues to take these particular areas and expand upon them so that you will have a better detailed picture of just what it takes in the way of, for example, the physics effort to build one of these reactors.

Representative PRICE. I think Mr. Durham has a question.

Chairman DURHAM. Mr. Simpson, this is an excellent statement. Personally, I have enjoyed listening to it. We all realize the difficulties in a brandnew development. However, is there any way you can arrive at a percentage as to the amount of conventional development that you can apply to the development of a reactor? Would you say it is 90 percent that is new and 10 percent conventional of that which has been worked out prior to this development process?

Mr. SIMPSON. With respect to the *Nautilus*, I hesitate to say that a hundred percent was developmental so I will back off just a little bit. However, there was scarcely a single item of any type that could be taken off the shelf; that had been used and could be used, therefore, in the *Nautilus*. Almost every item was developmental well in excess of 90 percent.

Admiral RICKOVER. May I answer that question, sir, because there is something that goes beyond what they did here. I can state unhesitatingly that I don't think there was a single item in the entire propulsion plant that didn't have to be developed.

Chairman DURHAM. I asked the question because I don't think people at large realize that fully. They think a lot of this work has been accomplished before.

Mr. SIMPSON. For example, even the steam plant for the *Nautilus* was new. No steam plant had ever been put on a submarine before. No steam plant, therefore, had ever run at these submerged depths. So a simple item like a condenser, which on a surface vessel operates at just a few pounds pressure, must operate on a submarine at many hundreds of pounds pressure. Take a simple thing like the safety valve. The steam system, instead of just opening and blowing the steam into the air, must open and blow it into the ocean. You can go on from there. All of the valves that we used in the *Nautilus* in the reactor plant had never been built before. The same is true of the pressure vessel; in fact, all of the components. High-pressure water had not been used in this way to any degree in the United States. High temperature water is, of course, used in boiler plants, but it is a different temperature and different degrees of corrosion are required. Therefore, the components are different in order to be suitable for a reactor.

Chairman DURHAM. Would your statement apply generally to all reactors?

Mr. SIMPSON. Yes. Obviously, they are less developmental as each succeeding reactor is built so it is difficult to assign a percentage to a new submarine today. The pumps that went into the Shippingport plant are much larger than the *Nautilus* pumps and, therefore, the mere fact of size involved a considerable development. A reactor vessel from a small vessel moved into a large one would require a different type of plate. In fact, the plate for the PWR vessel was the thickest clad plate that had ever been rolled in the United States. Therefore, many of the plates had to be thrown away because they weren't suitable.

Chairman DURHAM. Since the *Nautilus* was the first one, could you estimate on a percentage basis what knowledge which you gained in developing the *Nautilus* could be used in developing the *Sea Wolf*?

Mr. SIMPSON. I am not familiar with the *Sea Wolf*.

Admiral RICKOVER. I think I could answer, Mr. Durham. Because in a naval vessel you have to get the smallest weight and space, I would say that we did learn something about the principles, but as far as the actual development of items it was entirely different. That is not only true of the *Sea Wolf*, which is a liquid metal plant, but it is almost equally true of all the other submarine and surface-ship developments. You will find with these different projects that there is hardly a single item in one that you can use exactly in another one because we don't have acres of space to put it in. Actually, when we undertake the development of a new propulsion plant for a naval vessel—and it is practically true of all nuclear-powered naval vessels—we have got to develop all of the items individually. It is not only true of the reactor plant. It is true of the entire plant including the steam plant, the turbines and gears and so on. For example, we had to develop special turbines on the *Nautilus*. We had to develop special gears. You might ask, "Why isn't that available?" It just isn't.

Chairman DURHAM. What I am getting at, Admiral, is this. The members of this committee are often faced with a question from an

individual who says, "They tell us the *Nautilus* is obsolete so what do we have after this investment of taxpayers' money?" That is the hue and cry. Can we make some estimate as to the knowledge we have gained through the development of the first reactor? It would help us if we could have some estimate or if some estimate could be worked out. I don't know whether it can be or not. I am just raising the question here as a matter of discussion because that money is invested in knowledge.

Admiral RICKOVER. Perhaps I could answer it this way. Actually we could talk two different ways: One is about the development principles and scientific and engineering knowledge; the other is for specific items.

From the first standpoint, unquestionably most of the technology which exists in the country today on pressurized water reactor plants has come out of the efforts of this laboratory and to some extent out of the Knolls Atomic Power Laboratory.

Representative HOLIFIELD. Where?

Admiral RICKOVER. The Knolls Atomic Power Laboratory, because they have been working for several years on the radar picket submarine which has a pressurized water reactor. When it comes to individual items, however, the people who are working on commercial pressurized water plants by and large copy what has been developed because they have room to do so. The General Electric Co., in their San Jose plant, have copied the design of a PWR pump, for example. They can afford to because they have the space in which to copy exact items, the principles of which have already been developed. However, when it comes to a shipboard plant we can't do that because we have the intolerable situation of weight and space so we have to take these items and redesign them. That makes a terrific load in getting one of these projects done. One of the members of your committee asked me the question from the money standpoint several years ago. I stated then and I will state unhesitatingly again that I think there has been more advantage to American industry from the work that we have done than the actual cost of these projects. There are the developments in metallurgy, not only in zirconium and hafnium but in stainless steel. We have taken the lead in the last 2 or 3 years in developing stainless-steel technology. This will be covered a little later.

I think that is what Mr. Durham is really getting at. I think there has been a net gain to the American economy from this effort which is above and beyond any material or national gain in having these plants.

Chairman DURHAM. I think we on the committee realize that fully. We, of course, have to have something that is a selling point when we get into these big sums of money.

Admiral RICKOVER. If you would permit me, I would like to add subsequently to the record a list of these things we have contributed to the American economy.

Representative PRICE. I think that is an excellent idea. Will some of the speakers who follow cover what you have done here at Bettis in the development of new alloys and new materials?

Mr. SIMPSON. Yes sir.

Admiral RICKOVER. If that is satisfactory, sir, I would like to submit that list.

Representative PRICE. We would like to have it very much.
(The information referred to follows:)

DEVELOPMENTS IN THE NAVAL REACTORS AND PWR PROGRAMS WHICH ARE APPLICABLE TO OTHER CIVILIAN PROGRAMS

This report summarizes some of the developments in the naval reactors and PWR programs which may prove useful to others. However, the major contributions are broader than can be indicated by a list of items. For example, working out with the AEC's Safeguards Committee how to analyze the safeguards problems associated with the first reactor in the world to produce large quantities of useful power (the Nautilus prototype at Arco, Idaho); the first power reactor to operate near heavily populated areas (the *Sea Wolf* prototype at West Milton, N. Y.; the first reactor to power a ship (the *Nautilus*)—many of the precedents worked out for these problems can now be followed by others.

A similar situation exists for the development of techniques for power reactor design . A methodolgy has been worked out involving large-scale digital computers, mockup and flexible nuclear assemblies, large apparatus for testing fuel elements under simulated plant conditions of radiation, heat generation, temperature, and flow; specifications and equipment for testing all of the specially developed so-called conventional components, such as pumps, valves, and instrumentation.

The information below is grouped into three categories: Techniques and basic information, materials, and equipment development.

CONTENTS

I. NEW TECHNIQUES AND BASIC INFORMATION

1. Naval reactor technology handbook series

Interim and internal technical documents in the naval reactors program may not always be helpful to a person in a civilian reactor program because—

(*a*) Such documents often contain information which is fragmentary, unevaluated, or even data which later proves to be incorrect.

(*b*) Such documents usually contain military design information; the person in question may not be entitled to receive military information.

To reconcile these facts against the real need of civilian reactor groups to obtain information developed in the naval reactors program, a series of reactor technology handbooks is being prepared. Virtually all of the information developed in the naval reactors program which is applicable to civilian reactors is being published in this manner. By editing and by recalculation of sample problems, military information can be avoided and nearly all of the technology can be released. An important feature of these books is that work in each field is reviewed by people actually working in that field, and evaluated information is published rather than possibly conflicting or confusing data. The meaning of the data is also discussed.

The following handbooks have been published to date:

Liquid Metals Handbook	1st edition, June 1950; 2d edition, June 1952; 3d edition, June 1955; 2d printing, November 1955.
Metallurgy of Zirconium	July 1955.
The Metal Beryllium	July 1955.
Bibliography of Reactor Computer Codes	Dec. 1955
Reactor Shielding Design Manual	Mar. 1956.
Corrosion and Wear Handbook for Water-Cooled Reactors	June 1957.

Currently in preparation:
Naval Reactor Physics Design Manual
Heat Transfer and Fluid Flow Manual
Reactor Core Design Manual
Reactor Plant Piping Handbook
Radiological Aspects of Naval Nuclear Propulsion Plants
Hafnium Handbook
Irradiation Testing and Hot Lab Techniques
Nuclear Fuel Elements

2. Basic heat transfer research

For both sodium and water it was found at the beginning of the naval reactors program that basic data on physical properties, heat transfer rates, and pressure drops were not known with sufficient accuracy over the necessary range of operating conditions. In particular, the problem of heat transfer under transient conditions required study. Therefore, for several years basic experimental and theoretical work on heat transfer has been underway in the naval reactors program. The sodium work has been reported in the Liquid Metals Handbooks, and several new analytical methods, for example for natural convection in irregular shapes and for thermal shock caused by rapid temperature changes in the liquid, have been developed and reported. For water, better measurements of the pertinent physical properties, heat transfer rates without boiling and with the various possible modes of boiling, pressure drops with and without boiling, and limiting conditions beyond which fuel element meltdown can occur, are being studied. This work is being done both with electrically heated test sections and with specially instrumented fuel assemblies in the Naval Reactor Facility in Idaho. The variables affecting heat transfer in the reactor are now being added to the reactor physics equations so that an entire reactor heat generation and heat transfer problem can be studied as a single entity on a large-scale digital computer. These techniques should be valuable to other reactor designers. A handbook on heat transfer and fluid flow for pressurized water reactors is now in preparation.

3. Reactor physics

The naval requirement for a compact reactor of high performance necessitates that heat generation rates be calculated at many locations within the reactor core, for various times throughout the reactor life, and with various assumed casualties such as stuck control elements. A procedure for analyzing reactors in this detail is being developed using digital computers for calculations, in combination with experiments with laboratory assemblies of uranium and other materials designed to simulate, from the nuclear standpoint, characteristics of the operating reactor. Many of these techniques are now being used by other reactor projects.

In the course of this development several new physics concepts and techniques have been worked out. Some of these are listed below:

(*a*) *Seed and blanket principles.*—This is a concept whereby a natural uranium reactor, which cannot operate by itself in ordinary water, is kept going by neutrons leaking from a U–235 reactor. The resultant combination permits power to be extracted from natural uranium and also decreases the amount of control required.

(*b*) *Power flattening methods.*—By use of different concentrations of fuel and of poisons in different parts of the reactor, the generation of heat throughout the core can be made more uniform, and thus the core volume and the uranium content can be utilized more effectively.

(*c*) *Nuclear constants.*—Many nuclear constants have been measured more accurately for the naval program and the data are now available for other reactor designers. An example is the poisoning effect of xenon, a particularly troublesome fission product.

(*d*) *Epithermal reactors.*—The physics of reactors operating with neutrons of intermediate energy was largely unexplored prior to the development of the *Sea Wolf* reactors. Many of the physics constants and analytical techniques developed for it are applicable to the civilian fast reactor program.

(*e*) *Slightly enriched reactors.*—In exploring methods to obtain maximum utilization of U–238 in a reactor, a program for exploring slightly enriched reactors was undertaken by Bettis plant with help from Brookhaven National Laboratory. This program developed information and methods of analysis which can be used by other civilian reactor programs.

(*f*) *Large-scale digital computers.*—Most of the computation methods developed for naval reactors and the computer codes for implementing them are sufficiently general to be used in civilian reactor programs. A book of these computer codes was published by the Naval Reactors Branch and is being kept current by a nuclear codes group set up for the purpose by members of the American Nuclear Society. Arrangements have been made with computer manufacturers to supply punched cards and instruction books for these codes, without charge, to anyone requesting them.

4. Reactor design

Instruments have been developed to measure temperature, waterflow, and neutron flux at many locations inside a reactor core. This will permit more accurate study of how a reactor operates. Cores for the pressurized water reactor and for naval prototypes will all have such instrumentation.

The following are some particular developments in the naval reactor design field which are of possible application to civilian reactors:

(*a*) Use of airflow techniques for establishing the flow distribution through the core and hydraulic forces on control rods.

(*b*) Establishment of pressure drop characteristics of waterflow when some parts of the reactor are locally boiling.

(*c*) Development of a method for identifying and locating failed fuel elements. This required development of sampling means, identification of the influence of piping characteristics on the system, and establishment and proof testing of means for measuring delayed neutrons.

(*d*) Computational techniques for defining the shutdown requirements arising from the simultaneous and sequential loss of pumps during an assumed casualty.

(*e*) Establishment of the feasibility of and defining the conditions under which labyrinth seals can be used for controlling water leakage in the internal parts of core structures. Previous applications of labyrinth seals were generally limited to steam and gases.

(*f*) Computational techniques for including nonnuclear variations in fuel element properties in defining operating limitations of a reactor. This includes such effects as fabrication tolerances, warpage characteristics, maldistribution of flow, and uranium density variations. Both local and average influences are accommodated.

(*g*) Contributions toward understanding the phenomena associated with exothermic zirconium-water reactions, and their implications to reactor safeguards.

(*h*) Efforts to identify, measure, and take into account local neutron flux peaking caused by water channels adjacent to fuel elements, which have proved to be a highly important design limitation.

(*i*) In the general fields of heat transfer and hydraulics, data have been published from many experiments that have been conducted on flow mixing, flow coastdown, decay heat, loss of coolant, boiling, and parallel channel flow.

(*j*) Development of a mechanism which provides partial shutdown of the reactor to permit rapid recovery from inadvertent shutdown signals or easily corrected casualties.

5. Pressurized water reactor technology

The problem here was to provide a hermatically sealed system into which highly purified water could be introduced, in which continuous purification of water could take place, and which could be kept at a pressure higher than the boiling point of the hottest spot in the reactor. Build-up of radioactivity in the system outside the reactor and deposition of corrosion products on heat transfer surfaces had to be held to a minimum. The motion necessary to circulate the water, to move valves and reactor control elements, to sense and to transmit temperature, pressure, flow and position information—all of this had to be transmitted from within the system to control and power equipment outside, without violating the all-welded high pressure boundary. The particular

components to accomplish these various jobs are discussed in section III. Below are listed some of the developments of this technology which may have application to civilian reactors. This information is reported in the Wear and Corrosion Handbook published by the Naval Reactors Branch, June 1957.

(*a*) The adaptation of a bypass purification system using ion exchange resin for control of water purity in a high temperature water reactor system.

(*b*) The application of controlled alkalinity in a reactor coolant system to minimize general corrosive attack and deposition on heat transfer surfaces in a radiation field.

(*c*) Use of lithium-form and ammonium-form ion exchange resins in the purification system to provide alkalinity control compatible with the characteristics of pressurized water reactors.

(*d*) Use of dissolved hydrogen in the water to suppress water dissociation in reatcors, a phenomenon which can lead to unsatisfactory water conditions.

(*e*) Analytical methods and equipment for pressurized water reactors, including a high pressure conductivity cell and techniques for determining dissolved hydrogen and dissolved oxygen in high temperature water.

(*f*) High temperature purification media are presently under development with the objective of eliminating the need in the purification system for heat exchangers and overtemperature protection.

6. *Sodium reactor technology*

A new technology was built up to permit handling of radioactive sodium on a large scale at high temperatures. Methods had to be developed for maintaining high purity, insuring leak-tightness, and providing control of flow and temperature. Basic data were obtained in some cases up to 1,500° F. on corrosion, transport of radioactivity, self-welding of contacting surfaces, bearings, seals, sampling, analysis and purification of sodium, and maintenance techniques. Some of the major components developed are discussed in section III. Heat transfer in sodium was found to require new theoretical treatment, since the standard equations used for lower conductivity fluids such as water and air were not applicable. This information is reported in the 3 editions of the Liquid Metals Handbook published in 1950, 1952, and 1955. Analytical techniques for determining minute quantities of impurities in sodium were developed. Methods for cold-trapping oxides from the sodium to decrease corrosion were also developed.

7. *Testing fuel elements*

The most developmental, most expensive, and most critical part of a reactor plant is generally the reactor core itself. The problem of proof-testing the nuclear fuel elements is extremely difficult, since the environment of heat generation and radiation cannot easily be simulated. A means for installing pressurized water test loops into reactors was developed whereby most of the appropriate conditions could be simulated. The equipment required to achieve and control this environment has now become reasonably standardized and the technique is being followed by others. In particular the concept of initiating deliberate failures of various kinds in the fuel element to study the growth of a flaw from a minor to a serious one has proved useful.

8. *Reactor control and safety*

The problems of controlling a nuclear propulsion plant were largely unexplored when the first naval reactor designs were begun. Fast-acting reliable automatic control equipment was developed.

The safety problems associated with operation of power reactors had to be defined and explored. Information has been obtained on such general problems as chemical reaction rates of sodium and of zirconium with water and with air, flammability and explosiveness of mixtures of hydrogen with steam and air, and rate of heatup of a reactor when the coolant is suddenly lost. Much of the information developed during these studies has been brought together and reported in a series of reports on the safeguards analysis of the PWR plant. These reports are unclassified and will be available to the general public after they have been reviewed by the AEC Advisory Committee on Reactor Safeguards.

II. MATERIALS

1. *Zirconium and its alloys*

Zirconium was selected as a reactor structural material for pressurized water reactors because of its favorable nuclear properties and corrosion resistance.

In 1948 only a few thousand pounds of crude zirconium were produced in the United States. In that year only 86 pounds of refined zirconium were produced, which sold for about $200 per pound. A production plant for refined zirconium was built and operated at the AEC's Bettis plant. Steps have since been taken to get several commercial producers to begin production. Today the production of sponge zirconium is about 100,000 pounds per month, and the cost has dropped to about $11 per pound.

To further improve the value of zirconium, an alloy called zircaloy-2 has been developed. Zircaloy-2 is cheaper than pure zirconium and has improved corrosion and mechanical properties. An additional benefit of this alloy development was the arc melting technique developed by the Bureau of Mines for making zirconium alloy ingots. This arc melting technique has since been applied to titanium melting by the titanium industry. In the nonnuclear field zirconium may prove useful to the chemical industry because of its excellent corrosion properties.

To disseminate information obtained from the zirconium program, a handbook of over 700 pages was published in 1955.

2. Hafnium

Hafnium is a byproduct of zirconium refinement and had few uses when it first was separated in quantity. It was known to have excellent mechanical properties and corrosion resistance, similar to zirconium, but unlike zirconium to be a strong absorber of neutrons. Hafnium has since proved to be an excellent control-rod material for pressurized water reactors. Hafnium may also find uses in nonnuclear fields because of the very high melting point of its compounds and because of its heavy weight (greater than lead). A handbook on hafnium, its properties, fabrication methods, and other technical data, is now in preparation.

3. Other neutron absorbers for reactor control

To stretch the supply of hafnium a program was begun to develop alternate control rod materials. The principal materials studied were boron in stainless steel, boron in titanium, and silver alloys. Although pure silver dissolves in hot water, the addition of cadmium and indium to silver prevents this corrosion. These elements are also beneficial from a nuclear standpoint. The resulting alloy is cheaper than hafnium and may find use in commercial nuclear reactors.

4. Nuclear fuel materials

The naval reactors and PWR programs have worked on the development of uranium zirconium, and uranium oxide fuel materials:

(*a*) *Uranium-zirconium.*—Uranium zirconium has been developed as a fuel alloy material. This alloy has been shown to be capable of producing heat at a high rate for a long time. A large fraction of the fuel can be used up while still maintaining the strict mechanical specifications for reactor fuel elements.

(*b*) *Uranium-oxide.*—Uranium oxide has been developed as a fuel material and it will be used in rod form in the PWR core. This material has several desirable properties. It is inert and does not dissolve in water. It is dimensionally stable under irradiation. Compared with uranium alloys, it is less expensive to make and to fabricate into fuel elements.

Methods of using uranium oxide in plate form are also being studied.

5. Unlubricated moving parts for pressurized water reactors

To develop satisfactory mechanisms which required moving parts to operate in highly purified reactor water systems necessitated development of a new techology. Bearings, valves, control mechanisms, and various locking and latching devices in and near the reactor were involved. Satisfactory materials and combinations of materials for these various applications have been developed, along with equations defining the tolerable clearances, bearing loads, temperatures, torque, and other limiting criteria which determine operating characteristics.

The data on this program are reported in the Wear and Corrosion Handbook published by the Naval Reactors Branch, AEC, June 1957.

6. Stainless steel for reactor systems

A program was carried out to develop conditions under which commercially available stainless steels could be utilized in pressurized water reactor systems. Corrosion data, static and dynamic, effects of radiation and of chemical composition of the water, and other pertinent data were developed. The use of

stainless steel for this purpose has now been demonstrated and the information is being used by other pressurized water reactor plant designers.

7. Materials for handling high-temperature liquid sodium

A program for developing materials for handling liquid sodium and sodium-potassium alloy at temperatures up to 1500° F. was carried through in both laboratory tests and large-scale plant equipment. Springs, bellows, bearings, and valve parts were studied from a materials standpoint and satisfactory materials for these purposes were developed. This information has been made available in the unclassified Liquid Metals Handbooks series.

III. EQUIPMENT DEVELOPMENT

1. New vendors for nuclear equipment

Approximately a year and a half ago the AEC's Bettis plant was the only organization equipped to build reactor cores for pressurized water naval reactor plants. Steps were taken to acquaint industry with the requirements for fabricating these reactor cores in order to build up other sources of supply. The criteria used in considering prospective core manufacturers were:

(*a*) The company must have the necessary privately owned facilities or be willing to provide these facilities at no expense to the Government.

(*b*) The company must be willing to train personnel.

(*c*) The company must be willing to compete on a fixed-price bidding basis with other companies.

Today, there are five companies which are acquiring the necessary facilities, trained personnel, and capability to manufacture complete naval reactor cores. Fixed-price competitive contracts have already been let for five submarine cores, and competitive fixed-price bids for several more submarine cores of another design are now being reviewed by the Government prior to contract award.

For so-called conventional equipment, a somewhat similar path was followed. Starting with the procurement of equipment for the *Nautilus* prototype, the naval reactors program has worked toward the development of more than one source of supply for components of nuclear propulsion plants, anticipating the time when every item could be purchased on a competitive fixed-price basis.

Reactor plants for 5 fleet-type nuclear submarines (2 in the fiscal year 1955 and 3 in the fiscal year 1956 shipbuilding programs) were the first ones to benefit from this effort.

The estimated cost of these five reactor plants is $24,779,524, exclusive of (*a*) minor components and installation work which are covered by appropriate construction contracts with the shipbuilders, and (*b*) steam machinery and reactor cores which are being purchased competitively under separate contracts.

With the exception of the first core for these submarines which is being fabricated at the AEC's Bettis plant, and some plant control and instrumentation equipments for which development work was still under way, the remaining 4 cores and all other reactor plant components for these 5 submarines are being furnished on a fixed-price competitive-bid basis.

Approximately 300 subcontractors and first-tier suppliers are engaged in furnishing these 5 reactor plants.

It is expected that other reactor programs will also benefit from these actions.

2. Nuclear reactor cores

The following list includes some of the items developed in the naval reactors program in the field of reactor-core fabrication which appear to have application to civilian reactors:

(*a*) Nondestructive testing techniques for the inspection of clad fuel plates, fuel rods, and fuel assemblies. These include ultrasonic, eddy current, X-ray, and mechanical methods.

(*b*) Production methods for forging, rolling, extrusion, and other metalworking processes necessary for the fabrication of complex zircaloy shapes.

(*c*) Fabricating techniques for seamless zircaloy tubing and manufacture of such tubing for high-pressure in-pile test loops, as well as for PWR fuel rods.

(*d*) Welding techniques for joining zircaloy to zircaloy. This includes the design and manufacture of remotely operated welding chambers.

(*e*) Techniques for arc melting homogeneous zirconium-uranium fuel alloy, including the design of new types of furnaces.

(*f*) Manufacturing techniques for zircaloy-clad fuel plates. This includes cladding by roll-bonding and edge flanging techniques.

(*g*) Methods for joining fuel plates into fuel assemblies maintaining accurate spacing of the plates. These include both fusion welding and resistance welding methods.

(*h*) Standardized high-pressure hot-water and steam corrosion-testing techniques for reactor fuels and cladding.

3. Components for pressurized water reactors

Even so-called conventional components such as pumps, valves, and heat exchangers, when used in a reactor system, were found to require complete redesign and development. For example, in order to operate pumps in a pressurized water system without seals, a canned rotor pump was developed in which the rotational power is transmitted magnetically through a welded can. A similar principle is used to operate solenoid valves in the system. The major valves are powered hydraulically by the reactor coolant itself, which in turn is actuated by a solenoid pilot valve. The control mechanisms which move the reactor control elements also operate without seals. In addition, all of the moving parts and bearings surfaces in these reactors are designed to permit replacement without major maintenance. These components have been widely reported in the unclassified literature and are already used in many reactor systems, test facilities, and other systems requiring hermetic sealing of a dynamic system. The pumps are now being used as recirculation pumps in high-pressure commercial boilers, and may also find use in the chemical industry.

The naval reactors laboratories are working with manufacturers of boilers and heat exchangers to stimulate development of designs and materials for heat exchangers which can provide the high integrity essential to a reactor plant. This program is expected to have some influence on the design of conventional heat exchangers. Similar programs with industry are being carried out for pressure vessels, heavy forgings, castings, and plates.

4. Components for sodium reactors

When the naval sodium reactor work began, a similar equipment problem existed for sodium as for pressurized water, but with the factor of high pressure being replaced by one of higher temperature and a less understood chemical environment. Seals using frozen sodium as a barrier were developed. Electromagnetic pumps with no moving parts were developed for high pumping capacity against high head. Valves of several sizes and types have been developed which operate satisfactorily. Equipment of this type and the design principles behind it have been discussed in many unclassified papers and are being used by civilian reactor projects.

5. Nuclear instrumentation

Nuclear instrumentation, when the naval reactor designs were begun, was delicate, complex, and handmade. Rugged, stable, wide range, interchangeable, and maintainable equipment had to be developed. Specific developments completed or underway are:

(*a*) Development of reactor control circuitry to operate in the power range without any electron tubes.

(*b*) Use of standardized parts to decrease size, cost, and simplify maintenance.

(*c*) Development of temperature detectors for use in high-radiation and high-temperature regions.

Representative HOLIFIELD. Mr. Chairman, I would like to ask Mr. Simpson or Admiral Rickover a question in an effort to narrow the general knowledge down to a specific problem. How much of these techniques which you have developed in your pressurized water project, for instance, can be carried over into a sodium reactor or do you face a completely different set of problems—a different set of designs in your sodium or metal-cooled reactor?

Admiral RICKOVER. Yes, sir; you do. You use different material by and large with every different type of coolant. For instance, in a sodium plant you have beryllium as a moderator. We use no beryllium in water plants. You use stainless steel in a sodium plant, but the qualities in stainless steel that you want in a sodium plant are different than the qualities you want in a pressurized water plant. Sodium, for example, in noncorrosive as far as stainless steel is con-

cerned. Water is corrosive, so that in this respect sodium has an advantage. Sodium, if it touches air, burns. Water, if it touches air, does not burn. The physics is entirely different so you might say that you have two completely unrelated problems.

Representative HOLIFIELD. Do you have to develop a completely different technology when you change from one of these reactors to another.?

Admiral RICKOVER. When you change your coolant you have an entirely different problem. Of course, there are some things that you know in general about metallurgy and some things about physics, but by and large it is as different as day and night between two different coolants.

Representative HOLIFIELD. In starting a new type of reactor then, you almost have to start from scratch and go through the same painful process that you went through on the *Nautilus* or is there a certain ability on the part of people who have done a reactor to know the types of problems involved so that they are starting with a more professional approach than just coming from building airplanes, for example? The coolants and materials may be different, but you do know the types of problems so you are more efficient in handling them· You know the fields of inquiry but you still have to do the development.

Mr. SIMPSON. There are certain areas in which you get some advantage. For example, thermal reactors have certain kindred—they are cousins. A sodium reactor has a different energy spectrum, therefore the physics is radically different. However, a gas-cooled reactor, like a thermal reactor has certain similarities to a pressurized water reactor in the physics. Thus some of the information you get, some of the codes for computers are useful.

Admiral RICKOVER. We have had to make a lot of studies in each reactor project which will help other projects, particularly on materials. For example, we recently completed a study: We tried to get away from the use of helium as a cover gas. We wanted to use nitrogen instead. We have been studying this thing for 2 years and we have found nitrogen may have bad effects on account of nitriting steels. If somebody comes up with the idea of using nitrogen as a coolant in a gas-cooled plant, we have information as to the deleterious effect that nitrogen may have. There are basic things you learn and certainly any organization that has become proficient in designing reactors may develop a sort of feel for what is required. It is as though you were starting a clerk somewhere. Obviously a person who had been through high school would be better than someone who has never been to school at all. You might say you have people who are through the high-school stage so that they can understand what you are talking about. That takes a long time in this game, Mr. Holifield, to really understand what you are doing. That is the sort of thing we have to have in a laboratory of this type.

When these people put out a reactor it doesn't have a lot of acres. They have to design it exactly. If we decide that it is going to have 2 fuel elements and so many control rods, it has to work with 2 fuel elements and that many control rods because there isn't any space for any more than that.

Interestingly enough we went critical—that is, in the *Nautilus*—the new core went critical exactly in the way we had calculated. We have

to because our ships, particularly our submarines, have a limited weight and space. If we don't meet it, she can't submerge—she will sink. We are getting into this game in a very, very thorough way. We must know what we are doing to the very last thing which is something you don't have to have in a lot of other plants. So our design must be extremely accurate and painstaking.

To get back to your original question, when you put a new coolant in a reactor you have a tremendously big problem.

Representative HOLIFIELD. Does that carry over into heat transference as well?

Admiral RICKOVER. Yes, sir. Let's take gas as compared with water. Gas is normally a poor heat transfer medium. That means you have got to have a much larger pumping power for gas than for water. You have to make many calculations and this is particularly true for a naval vessel.

For a land reactor of the Calder Hall type I would design the pressure vessel as large as it could be made. I would have extra fuel elements available in case it didn't work. I would keep on adding fuel elements until it did work.

This was a very penetrating question. Every time you start a new reactor—if you start a homogeneous reactor, you have different problems than you have gotten into before.

Chairman DURHAM. How does that apply to your core?

Admiral RICKOVER. The core is going to be completely different for the homogeneous reactor than it is for a gas-cooled reactor or for a pressurized water reactor.

Chairman DURHAM. In other words, that is a new job, too?

Admiral RICKOVER. Yes sir, that is a completely new job. I think you should understand it is completely new.

Representative HOLIFIELD. Actually in place of being able to do it experimentally like the British have been doing it, you have had to cover that point of accomplishment in your laboratory so that when you did install the rod type, you had already passed the experimental state. How did you scale up your computations to know that the *Nautilus* would go critical at a certain point?

Admiral RICKOVER. That was in our basic philosophy. We say we will not go to these intermediate stages in our program. We will pick a ship that we want to put the reactor in, and we will start designing those very items. At the stage of testing we will build a prototype. That is where the prototype comes in. We say this prototype will be exactly the same as the ship, and we have got to make the prototype work.

The other approach is to start in with little things, but you do not get dimensional similitude in the reactor game. For example, if you have an automobile storage battery, from that we can go and design a submarine storage battery which has about 50 times as much volume. There are many things in engineering which can be done this way. But not with reactors.

Representative HOLIFIELD. I don't understand. Why?

Admiral RICKOVER. There are two main reasons. One is that you are dealing with phenomena. There are these little phenomena that you have going on in atoms where you are concerned with a thousandth of an inch, and just a couple of thousandths of an inch may make a lot of difference in the control and the way the whole thing works. Gen-

erally in engineering you have gross effects. Take a valve. Let's say that it is good for 100 gallons of water a minute. I can take one that is designed for 100 gallons of water a minute and I can pretty much figure out a design for one that will take twice as much water with a very good chance of success, but this is not true with reactors. The only way I can do this in a reactor is by making it larger than necessary. If you make it very big and you have lots of room, then essentially your reactor is a critical experiment and not a real power reactor. Take the EBWR. They computed they would require 48 fuel elements. They actually required 78 to make it go critical. We can't do that in a naval vessel.

To get back to your original question we build something and we test it in every way we can. For example, we ran the first pumps as much as 10,000 hours before we actually installed them in the prototype. We rigged up equipment here at Bettis. We kept on testing. We rolled them 30° from side to side while they were running. There was pitch under all of these conditions too. We tested them in a live submarine under depth-charge conditions. Congress permitted us to use an old submarine, and we installed these pumps in the submarine. We exploded a 300-pound depth charge 30 yards away. The pumps kept on working. We tested a lot of stuff that way. That is how we learned.

Chairman DURHAM. Is there any way to determine the number of neutrons in a core?

Admiral RICKOVER. We know the neutron level in a core. In the prototype of Arco we have been running tests with what we call flux wires. We insert these wires in a core and we can measure neutrons. We actually know what goes on in the core. Incidentally, one of the reasons for the considerable expense is the vast amount of instrumentation that we are putting in so we can learn from future design. We have not looked at any of our plants as jobs that you just build to make it work. We have always borne in mind that we had to develop lessons for our own future and for the future of other people in the game. This is one thing that this laboratory has done a great deal toward. We have always been conscious that while we were trying to get a particular job done we had to learn lessons for the future. We had to find out why things were happening. Naturally you never do as much of that as you want to, but there has been a considerable amount of effort and money spent to develop basic information.

Chairman DURHAM. How about the speed of neutrons?

Admiral RICKOVER. The speed of neutrons depends on whether you have a thermal reactor, an intermediate reactor, or a fast reactor. All of the pressurized water reactors that we are designing here are thermal reactors; that is, they use slow neutrons. The *Sea Wolf* has an intermediate reactor. Thermal reactor neutrons have an energy level of about one-fortieth of an electron-volt. The *Sea Wolf* has about 5 electron-volts. Fast reactors have much more than that. They may be anywhere from 5 or so electron volts up to 100,000. All of our reactors except the *Sea Wolf* are thermal reactors.

Representative PRICE. Mr. Simpson, did you plan to tell us something about the size of the laboratory and the size of your organization?

Mr. SIMPSON. Yes, sir, after the various gentlemen have talked I will describe a typical reactor project. From that I will show you the number of projects and sizes.

Before we go on though, I would like to give one specific illustration of the problem of scale-up that the admiral mentioned. If you take a small reactor similar to the *Nautilus*, it has a negative temperature coefficient. If you keep making it larger and larger and keep everything relatively the same, somewhere you reach the point where it no longer has a negative temperature coefficient, but it has a positive coefficient. Instead of the reactor having inertia and tending to shut itself down and, therefore, being safe as the temperature goes up, it reverses and the power tends to rise. It then has a possible runaway condition. At that transition point you must change the design to maintain the negative coefficient, so what you have learned in the small one does not per se enable you to design the larger one, because a leakage of neutrons out of the reactor is strongly dependent on design geometry of the reactor.

Chairman DURHAM. Then there is no way to determine the efficiency of a reactor on the basis of size?

Mr. SIMPSON. This can be done analytically to the extent we are today competent. We are not yet, nor is anyone, competent to completely describe a reactor's performance with simply analytical techniques without experiments.

Chairman DURHAM. Actually you have to build it to get the full knowledge of its efficiency?

Mr. SIMPSON. Yes, sir.

Admiral RICKOVER. The next speaker is Commander Laney, who heads up the technical staff here for Mr. Geiger, the manager of the Pittsburgh area office of the AEC. As you may know, we have civilians here and officers from the Navy who are experienced in naval engineering, helping out in the field offices. Commander Laney works for Mr. Geiger and heads up the technical staff.

STATEMENT OF COMDR. R. V. LANEY, ASSISTANT TO PITTSBURGH AREA MANAGER, ATOMIC ENERGY COMMISSION

Commander LANEY. In my remarks, Mr. Chairman and gentlemen, I will attempt to point out some of the naval characteristics of a ship which influence the problem of the reactor, the reactor plant and cycle.

Each naval reactor project here has a specific end in view. It is intended to be installed in a definite ship at some definite time in the future. Because of the fact that the building time for a ship and the building time for a reactor and the reactor plant components are different, this means that the ship is partly built—it is almost entirely designed and it is on the building ways while the reactor and the reactor equipment are still being designed. Visualize the ship sitting there—its characteristics, its length, beam, its speed, its submergence depth—all are determined, frozen. The steel has been rolled and put together. The reactor designer meanwhile hasn't yet fixed his design and his components have not yet gone into production. This means that his task is very sharply defined for him and there is a very high premium on the success with which he does it.

Much is committed, in other words, before he reaches the point of committing his material to the manufacturing shop. The reactor designer then must conceive, develop, design, and produce a reactor which, when delivered to the ship, will fit into the reactor vessel which it has never seen before. That reactor vessel is resting in a ship which is a stranger, and the reactor, the vessel, the pumps, the heat exchangers, and the intricate control equipment must, the first time they operate in unison, operate correctly, so that the ship will have the necessary amount of power to produce the speed for which he has designed and which he has to come up with.

These remarks indicate perhaps how the reactor designer is given a very specific task, a very specific chunk of space and weight, performance, and criteria to meet. Long before he knows just how he is going to do this, other things contingent on that have been done. This accounts in a large measure for the very extensive development and engineering testing which accompanies and goes along with the reactor—just because the premium on this working and working right, as designed, the first time, is so high.

While you are here today you will see some of these large-scale engineering tests and with this in mind, you will understand why they are essential to carrying out the program such as I am describing. It is also true that we are by no means sufficiently able to predict the performance of a design as we would like to predict it. There is a good deal of the basic type of information still lacking. This means that it is all the more important that the engineering or performance tests are adequately and thoroughly done. Programs such as these, which span several years in time, in which the end result—the ship operating at sea—is closely and intimately linked with the design of even the components in the plant obviously call for a very closely knit system of program control in which even the seemingly more technical decisions are directly related to their influence on the ship. Will it adversely affect its weight? Will it adversely affect its speed, its safety or reliability? We, therefore, have developed a system of program control which has a rapid response time, which we hope detects quickly and corrects any of the work of design which gets out of line and which is not directed to the objective in view.

Basically the ship operating characteristics and the powerplant functional requirements are specifications prescribed by the Naval Reactors Branch in Washington. They are the working specifications to which work here is performed. Stemming from these original design objectives and working between NRB and the contractor there are developed successively refined plant designs beginning with the most tentative design in which what is feasible has to be distinguished from what is desirable but may not be feasible, so as to obtain the assurance necessary along the road ahead. These designs are then successively refined. The components, the systems of the plant are described analytically in words, and experimental programs are devised to test them at each stage of the way. The design decisions made have to be measured against the end product and its result upon the end product. All of the major design or technical decisions which are made in these programs are made essentially by agreement among the principal participants. That is the Atomic Energy Commission, the Navy, and Bettis. All major technical decisions are based on essential agreement. If there is a strong dissent

on the part of any one of these parties, the only way we feel it is possible to resolve it is by talking it through until essential agreement is reached. On the other hand, the lesser technical decisions which derive from the major ones are made in somewhat the same way in most cases—being referred back to our principal technical source of direction, the Naval Reactors Branch.

We have here at the site a joint AEC/Navy administrative and small technical group. This small group is responsible for administering the contracts under which the work here is performed and for assuring that the work is done within the prescribed procedures of the AEC and the Navy. Also this small technical group serves as a liaison between NRB and the contractor, attempting to interpret the objectives and clarify them. We monitor the work continuously so as to assure so far as we are able that it remain pointed toward the objectives we have and paced so as to achieve them in time.

Representative PRICE. Mr. Durham has a question.

Chairman DURHAM. Commander, I understood you to say that you have the hull of the ship before you begin designing or before you have knowledge as to how you can develop the reactor in a ship. Do you think that would apply to a plane as well as a ship?

Commander LANEY. I don't know the answer to that, Mr. Durham. I am not familiar with the manner in which planes and their engines are designed. In the case of the ship, the present building time for a submarine is perhaps 3 to 3½ years. That is good building time. In order to put off as late as possible the time when we freeze our reactor design, which is desirable to get the best reactor, we wait until the ship is a year or a year and a half along. Since we can build a submarine-type reactor in 12 to 14 months, we use that intervening time not to freeze the reactor, but to improve it. It is for this reason that the reactor goes into its manufacturing period after the ship has been completely committed and is in its principal characteristics fixed.

Representative HOLIFIELD. Mr. Chairman, I want to ask one question. Probably this question should go to Admiral Rickover. Could you explain very briefly what the composition of the Naval Reactors Branch in Washington is? I know you are the head of it, but how many people do you have? How many Navy people? How many civilians? What, in general, does it take in the way of qualifications from the Navy side to get in that Branch?

Admiral RICKOVER. As you know, the organization is such that my primary duty is in the Commission and I work for Mr. Davis, who is the Director of Reactor Development. I head up the Naval Reactors Branch. Our system of operation is quite different than any other branch there. We are not just building reactors. We have to build reactors, as Commander Laney has explained, that must fit in ships which have already been started. The Navy wants them to make so much speed which means so much horsepower so we are very limited. There are a lot of things we can't do. We have to work harder to make it fit.

The technical direction of our program comes from my organization in Washington. We make the more technical decisions as Commander Laney has said. Where there is an argument we have to fight it out. There has never been one time in this game that we have ordered anyone to do anything. Of course, ultimately you get to

questions where policy decisions are involved and then I make the final decision. That is where you do one thing or another. Ultimately, somebody in life has to make those decisions.

We have about 90 people in the Naval Reactors Branch. Most of them are very young. Several years ago when I started to hire people for our organization I found there were very few people who were qualified for our work. By "qualification," I do not mean, necessarily, their technical ability, but the desire to work long hours and to be dedicated to the job as well. At the state we were in we had to get people of that kind. So I came to the conclusion that first we should have a long training period. As a result of that the Commission finally set up the Oak Ridge School of Reactor Technology. We were instrumental in getting that started. There is no one in my organization who was not given special training. Everyone who comes into my organization must receive this special training.

We adopted the procedure of getting only young people. We get the best graduates from universities in the country. I have arrangements with deans of the various engineering and scientific schools whereby they recommend their best people. They come in for an interview. I am talking now of people coming from universities. They are interviewed by a board of four people. Each member of the board interviews them separately. Then I interview them. There is not a single person who comes into the Naval Reactors Branch, except secretaries, who do not have to go through this procedure. Our rate of acceptance even of these people who are so highly recommended is about 1 out of 4.

The same thing applies for naval officers. No civilian or naval personnel are ordered into this program. They are all selected. Admiral Holloway, Chief of Naval Personnel, realizing the importance of this program to the future of the Navy has made an exception to the normal procedures. He permits people to come in for an interview. We get engineering duty officers in once a year. Out of an application list of about 40 or so engineering duty officers, a board screens their records and recommends 15 or 16 to come in for an interview. They go through this process I have described. We will probably take 4 or 5.

Most of the officers in our program are young officers—Reserve officers—who have agreed to stay on for 4 years instead of the normal 2 or 3 years. We have been successful, in many cases, when their tour in the Navy is over in that they shift over into civil service. This is really one reason we take these young people in. We feel it is essential to get smart young people and train them in our way of doing things. I think it has worked out very well.

Representative Holifield. You are not reaching out then for topflight scientists. Actually you are training your own.

Admiral Rickover. A lot of topflight scientists are not topflight scientists. A lot of topflight scientists are that by reputation only. We can't afford to have people around who have reputations who don't work hard. We would rather have people who work hard and don't have the reputations. No, sir; we have been rather disillusioned.

Representative HOLIFIELD. This would indicate, then, it is on the capability to direct men into a certain field rather than to rely on the basis of what they had already accomplished in that field; would it not?

Admiral RICKOVER. If we get in people with more experience it takes too long to have them unlearn the bad things they know. We haven't got time for that. So we have come to the deliberate conclusion that it is best for us to take young people in who have not yet been out in industry and have learned the way industry or other organizations do things. We have our own way of doing things. A lot of people don't like the way we do business and we are very well aware of that, but there is no one in my organization who can't get out and get a job at a much higher salary. Very few of them leave though, so that is the proof of the pudding. I don't know whether I have answered your question.

Representative HOLIFIELD. It gives me an idea of the type of branch you have.

Admiral RICKOVER. I would like you to come up some time. I know you are all interested in education. I would like you to meet some of these young people, talk to them and hear what they say.

Representative PRICE. Thank you very much, Commander Laney.

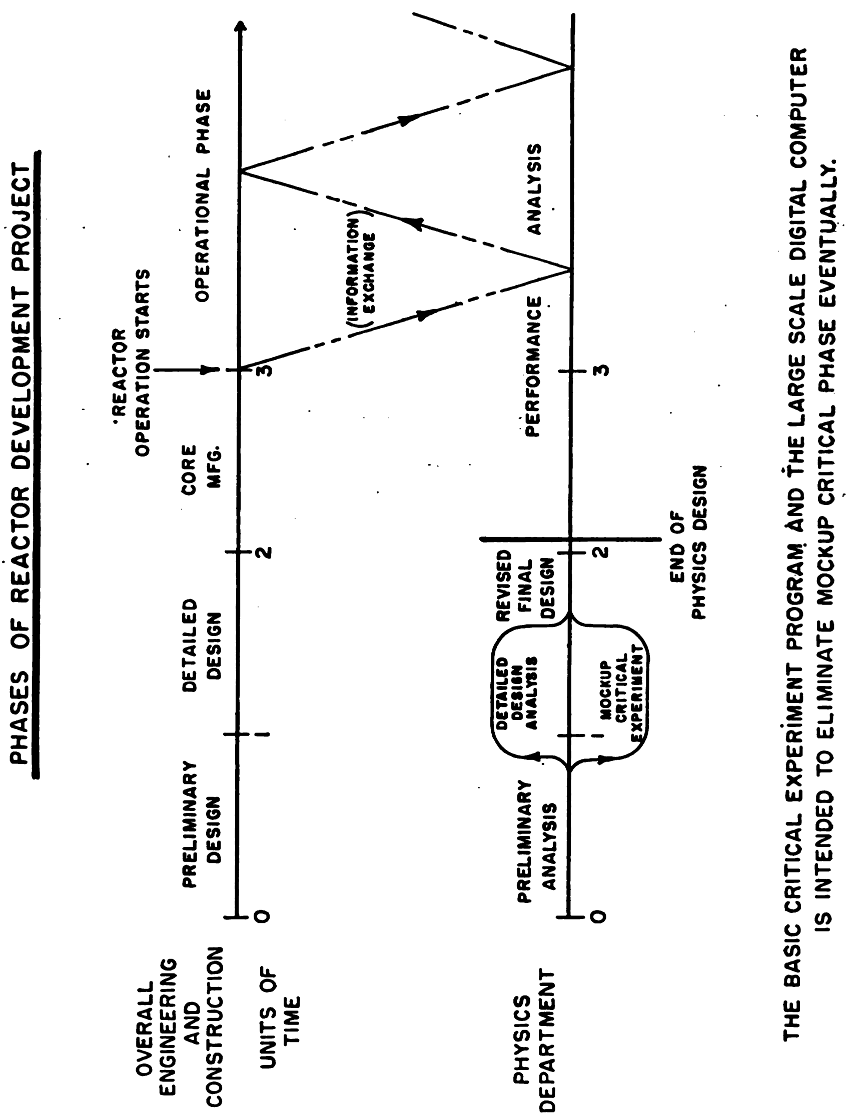
Mr. SIMPSON. I would like to ask Dr. Sidney Krasik, the manager of the Bettis Central Physics Department to discuss the physics aspects of reactor development.

STATEMENT OF DR. SIDNEY KRASIK, MANAGER, CENTRAL PHYSICS DEPARTMENT, WESTINGHOUSE ELECTRIC CORP.

Dr. KRASIK. Mr. Chairman and gentlemen, we plan today to show you some of the interesting things we have here at the laboratory and to tell you how we carry on our reactor design.

You will find a great many of the problems in the reactor design are centered and focused around the physics problems of a reactor. One of the things we want to show you is our critical experiment facilities. I thought perhaps I might take a few minutes to explain how the physics design of a reactor is accomplished, how it fits into the overall design of a reactor plant, the problems we face, the things we can do and the things we hope we will be able to do.

Actually it might be just as simple for me to make a few sketches on the board here and talk informally. Suppose we take the duration of a reactor project as being three units of time with a unit of time being more or less a year or so. This is the stage of completion of the project. The reactor core is now inserted in the ship and it is ready to go into operation so that is the operational phase of the reactor project. This is the engineering and construction phase. Something of the order of a year is associated with the core manufacture and installation in the plant. Another unit of time more or less of the order of a year is associated with the detailed design; that is the working out of the actual detailed mechanical problems. There are tremendous problems that have to be worked out in the preparation of the drawings—the release of these drawings for procurement of components.



There is left open approximately one unit of time on the order of a year for the preliminary studies which essentially fix the nature of the project. As Commander Laney told you it is about this stage of the game that the characteristics of the vessel have been fixed into which this reactor component will go. The freedom then which a reactor designer has; the freedom which a physicist has, is very limited. Indeed, all we have is this time here to decide how the reactor of which we do not yet have a good picture is going to work in that plant; how it is going to meet the final weight specifications; how it is going to fit into the space that is allocated and perform as predicted.

Let's take a look at this from the physics point of view. There have been several questions asked. Mr. Holifield asked a question about

scale up and similitude. I would like to go into that a little bit by indicating how the physics design is accomplished. The fact of the matter is, as Mr. Simpson has said, that we really don't know enough to sit down with pencil and paper and slide rule, a desk computer or even a larger automatic computer. We simply do not know how to sit down and calculate the properties of this reactor. We don't have that knowledge. We don't have that understanding of the way the reactor will operate.

The way that is accomplished then is sort of like this. This is the physics part of the overall reactor design. This is the overall reactor design. This is the physics part of it. You start out by making survey studies—trying to explore in a very rough fashion what you can do. You may spend some months doing that.

As you begin to see what it is that you are going to be able to do, what you are going to be able to meet, you can actually go into the preliminary design phase in which you begin to draw some pictures of what this reactor is going to look like. You can begin to make sketches of its size. You know what size reactor vessel it must fit into—dimensions and so on.

As soon as we have reached that stage we then proceed to go into a physics experiment which is an essential part of this design procedure. This physics experiment we call a critical experiment. It represents, as nearly as we can tell at this stage of the game, a nuclear mockup of the final reactor as we visualize it. Obviously at this stage of the game we don't know what the reactor is really going to be like so we begin this experiment with some degree of flexibility so it can be changed and modified as we learn more about the reactor.

At the same time, in order to proceed and gain as much time as possible, we actually go into a detailed analysis of the design on the assumption that we do know how to do it. That is rather than going into a detailed analysis and then into a critical experiment. Then correcting the detailed analysis, we carry them on in parallel in order to save something approximating a year in this overall procedure.

When the critical experiment—and we hope to show you several of these today—is in operation, we begin to get information which then gets put into the analytic part of the job. After, say, 8 or 10 months when the critical experiment has been constructed and it is ready to go, we find out we have made some pretty bad mistakes so we begin working back and forth between the detailed analysis and the critical experiment.

Then we go into the revised final design. This is the final design we make, and this has been released for manufacture. So you might say that as far as the physics design of the reactor is concerned, there was precious little flexibility back here even, because all of the characteristics—the size and so on—have been fixed and by the time you reached this point there is no further influence we can have on the design.

It would be a very serious mistake to stop that effort at this point. What really is needed is a followthrough on the effort and this stage which we might call the performance analysis. That is we continue the physics work. Now that we know what the reactor is going to look like, know its shape and size and some details of design, we actually begin to study in considerable detail what this reactor will

actually perform at. It may be at this particular stage of the game we can uncover a bug. If so, we are in a far better position to correct it than we would be if we waited until the reactor went into operation.

As soon as a reactor operation begins, the operational lifetime for performance, efficiency, and so on gets back into this. This performance analysis of the reactor, this followthrough on the project is an extremely important part. It is here you can make a great deal of progress for your technology. I might even cite an example. Admiral Rickover mentioned the *Nautilus* core. I think it is noteworthy that the principle that was incorporated which extended the lifetime of that core had, in effect, been suggested by a member of Admiral Rickover's staff. The suggestion was originally made and presented late in 1952, as I recall, after the first *Nautilus* core had been completed. There was nothing we could do about incorporating it in the first core then, but we proceeded to factor the information from the *Nautilus*—the Arco operation into that and during 1953 that principle was examined analytically. It then was incorporated into the prototype. That prototype was fully tested in the plant at Arco and now it is ready to be used in the *Nautilus* and do demonstrate its worth.

Chairman DURHAM. I have a question at that point. I suppose your analysis applies to all types of power reactors as well as to the *Nautilus*. Would it apply to all reactors?

Dr. KRASIK. If the procedure that is carried out in determining—in developing the reactor is the philosophy which we adopt here; namely, to make this time as short as we possibly can.

Chairman DURHAM. That is the point of course which disturbs us all. I suppose Westinghouse hopes to get into the position of selling reactors at some stage of this game. Looking at it as a hardheaded business concern which wants to purchase a reactor, how are we going to sell him that reactor on the basis of that kind of analysis? That is on the basis that all propulsion systems have to be determined more or less on the end product. You can't tell this concern whether or not this reactor will perform; can you?

Dr. KRASIK. No.

Chairman DURHAM. As I understand this analysis, you have got to go to a point where there are large expenditures of funds by somebody before you can guarantee to that purchaser that he is going to get performance out of the reactor?

Dr. KRASIK. That is for a developmental reactor.

Chairman DURHAM. That is right.

Dr. KRASIK. This analysis would certainly apply to the Shippingport plant where exactly the same type of development program is under way.

Chairman DURHAM. Here is my point. At the present time we have many companies throughout the United States looking at these things, coming in and making applications to the Atomic Energy Commission and starting in a small way. I don't see how we can ever sell a man a reactor on the basis of your analysis. If I was sitting on the board of directors of some company, I would consider this as a hardheaded businessman.

Representative PRICE. Doesn't this apply only to the first of any type of reactor?

Dr. KRASIK. What I wanted to emphasize, Mr. Durham, is that this is the way to carry out the development of the first plant of its class. This is the way the first Shippingport plant would be carried out. This is the way a new and advanced core for Shippingport might be carried out. It would not, however, apply to a duplicate plant in which all of the technology, all of the information developed here would be made available. Once you have reached this point and you know what this reactor will do you can copy it without doing any of this.

Chairman DURHAM. I realize that. Of course we are at a point of development in this country of having nothing but Shippingport at that point, you might say.

Representative HOLIFIELD. And where every type of reactor that is proposed must go through this uncertain and unpredictable stage and then operate it after you have completed the work. It has got to be operated over a period of time before you get a history of performance.

Dr. KRASIK. Exactly.

Admiral RICKOVER. We are still learning from the plant out at Arco. It is our most valuable tool. Again, let's go back to the dimensional similitude problem. The think is completely different than any conventional apparatus. You can build a turbine. After the first turbine worked around 1880, for practical purposes it was relatively easy to build a larger one. You didn't have to go through this. There were details you had to work out such as better manufacturing of buckets and fastening of buckets and the wheels and so on, but you didn't have to go through this. I don't know of any other scientific and engineering game where you have to go through this process.

Representative HOLIFIELD. You have stated that you started within the limitation of the whole—of the ship. Commander Laney explained that. Is there some advantage and if so, how much, to starting a new type of reactor without that limitation? I am thinking now of a new type of land-based power reactor. What is the advantage of not having to conform to a specific space?

Admiral RICKOVER. If you want to get a job done and have it done on time and have it work, then you had better tie the guy down within boundaries. You have to say, "You have got to produce a certain thing in a certain time." Otherwise he is going to take easy, dilatory methods. I think you will ultimately get more progress—much more progress out of this hard regimen than you get where somebody just builds something.

Representative HOLIFIELD. A hard regimen in performance and in time?

Admiral RICKOVER. Over everything, sir. That is the only way you are forced to find out what really goes on in this reactor.

Representative PRICE. It is better for the morale of your organization if they are working on a schedule.

Admiral RICKOVER. Better for the morale of the people who are working, but not for their wives and families, as I think some of these people will attest. However, that is a basic principle in performing any work of this kind. If you tell people to just build a reactor and, to use a figure of speech that they have got acres of space, they can go along and do anything. They are not pushed. When they try it out,

and if it doesn't work, they say, "We will do this and we will do that." But when you force scientists and engineers to stick to something that has got to work in exactly that way, then there is something happening every day and night. They have got to find out why as Dr. Krasik has been telling you. He has got to find out why these things are. We give him such tough limitations in space and in weight that he can't possibly do this unless he really learns why. That is the reason we are developing a science of reactors and reactor technology because we have had to find out why it works.

Chairman DURHAM. I was impressed by the statement of Commander Laney when he said that every reactor here was designed for a useful purpose.

Admiral RICKOVER. For a specific purpose.

Chairman DURHAM. In other words, something you can put in the storehouse.

Admiral RICKOVER. It either works or it is junk as far as we are concerned.

Representative HOLIFIELD. If you were designing it for a land-based powerplant, can you not tolerate more latitude in size?

Admiral RICKOVER. Let me answer that. No, sir. The thing that dictated the power output of the PWR was the maximum size of the pressure vessel that you could make. That was the largest one that American industry was capable of making. Incidentally that determined the basic design in the Calder Hall plant, also. They built what at that time was the largest pressure vessel for that pressure that could be built in England. Once you do that, the next thing you want to design and get is the maximum amount of power output you can. Your volume is fixed.

Representative HOLIFIELD. In this case your limitation was the technology of building the pressure vessel, just like in your submarine it is the space in the hull?

Admiral RICKOVER. That is right. I could have taken a different approach and said, "Fine. I have got the largest pressure vessel. I will just build a reactor. It will work and we will get out of it what we can." We didn't do that because we not only knew when we started out the maximum size of the pressure vessel, we also set the power for it. We didn't have to tie ourselves down, but we did tie ourselves down. Is that point clear?

Representative HOLIFIELD. It is clear.

Admiral RICKOVER. We tie everybody down because the natural human tendency is for everybody to create some kind of monopoly—that is to be let alone. We think that is bad—to let people alone.

Representative PRICE. Does that mean the maximum capacity of a pressurized-water powerplant in the future will be limited by the maximum size of the pressure vessel?

Admiral RICKOVER. No, sir; it does not mean that at all. When we said 60,000 kilowatts of electrical power, we wanted to give a figure that we thought we could meet. We are designing a new core based on a great deal of information that we have learned from the first one. We are designing a new one here which we think will give about a hundred thousand out on the same pressure vessel. There are many other things we have learned that we can do. Perhaps we can stand some amount of boiling in the reactor. Perhaps we can increase the size of the pressure vessel by learning how to get down to lower

pressures. There are a lot of other things. But basically the thing Mr. Holifield was asking about is the real major principle and how you go about doing the job.

Representative HOLIFIELD. I was trying to find out if the power-station people are going to be bound by limitations of one type or another the same as you are.

Admiral RICKOVER. Yes, sir. The General Electric Co. when they are building a reactor with only 1,500 pounds pressure—whatever it is—they are also bound. They are making the largest pressure vessel they can with 1,500 pounds pressure so they have already got that fence right there.

Mr. SIMPSON. There is another facet to that, sir, that I would like to bring out. Not only is there the limitation of the size of the vessel, but strange as it may seem, the actual design, manufacture, and installation of the pressure vessel takes more time than getting the core so that we have ordered and started cutting metal on the pressure vessel and even if we could have built a larger one, we were already building the one of that size.

Representative HOLIFIELD. You were committed.

Mr. SIMPSON. We were committed. Before the reactor design had reached the point where we knew as much as we wanted to about the power you could get out, the metal was rolled for the pressure vessel and at that point you can't change.

Admiral RICKOVER. It took 2½ years to make that pressure vessel.

Mr. SIMPSON. The only limitation of the larger vessel you could build is the limitation of the vessel you did build.

Admiral RICKOVER. That is the only way you can do it—if you set yourself a goal that you will have something working by a certain time. The other way you do it is to set a bunch of people designing cores and people designing a pressure vessel and sometime, maybe 2 or 3 years after they started, they get together and find they are away off. They would have to compromise at that time and you have to start all over again. It might take you 10 or 15 years before you get a reactor. You have got to set limits at some time and work to them or you will never get there. If you are working with small units, you can overbuild them. You are not concerned with the exact power you get out, particularly if it is a small order of power. When you start to work with large blocks of power or in cases where the reactor has to perform exactly, you sure have to be tied down. That is what really makes the trouble in this game. Outside of that it would be a very fine game to be in.

Chairman DURHAM. Suppose somebody comes to Westinghouse now and says, "We want a reactor that will produce 200,000 kilowatts of power." At what point could you tell that person that his plant would operate?

Dr. KRASIK. If this were the first plant of a type?

Chairman DURHAM. You have built a plant here at 60,000 kilowatts. Then someone comes in and says to Westinghouse, "We want 200,000 kilowatts."

Dr. KRASIK. Having done Shippingport and having operated the Shippingport plant we could probably now give a fairly good estimate back in here of what the feasibility would be of a 200,000-kilowatt plant.

Admiral RICKOVER. He said "feasibility" though. Be careful.

Chairman DURHAM. I am trying to get to the point where we can sell some of these.

Representative HOLIFIELD. You would be selling "feasibility" then if you actually went into the market to sell it. You wouldn't be selling "actuality."

Mr. WEAVER. This would be true, Mr. Holifield, until we have operating experience with any one of these plants.

Dr. KRASIK. I would like to add just one word to what has been said about setting the goals and setting the limits. Actually the important thing in reactor development is to explore the technology to find out what you are really up against. If you go down through a valley like a wandering river and take the easy place at each turn, you would not know what your limits are. You have to run up against the real limitations of this problem in order to find out what is going to stop you from doing something. I think from that point, quite apart from the time scale which I think you appreciate, the setting of goals is an important part of this job.

Chairman DURHAM. I think we are all trying to find out exactly where we are at in the development of these reactors. It seems from your statement that we are still in the development stage.

Dr. KRASIK. We are in a very preliminary development stage.

Chairman DURHAM. Preliminary?

Dr. KRASIK. Preliminary and it is quite unsatisfactory to all of us to go through as cumbersome and time consuming a process as this to get to a reactor state. All of us are straining to do something to eliminate this prolonged elaborate procedure.

For example, this critical experiment—quite apart from the money that it costs to build, and it is a very formidable sum of money indeed—takes somewhere on the order of 10 to 15 months in the schedule to construct. As you will see from your visit later today, it must be a rather good duplicate of the plant of the reactor that you intend to build.

Chairman DURHAM. When the Shippingport reactor is completed and operational, will it still be in the preliminary development stage?

Dr. KRASIK. We are trying to do something about this, sir. We are trying to develop the reactor physics to a state where it isn't an art where somebody guesses and puts in a lot of costly time-consuming experiments. We are trying to do a different type of critical experiments, which we will show you, and which are basic critical experiments. From these we hope to get not what is the overall properties of the reactor, but what are the individual things that contribute to these properties. Furthermore with our large scale digital computation ability we are hoping to advance the theoretical so that the combination of these two will in the course of, perhaps, 3, 4, or 5 years enable us to eliminate this completely from the reactor development schedule and to start in at a survey study. This would give you the flexibility at that stage of the game to predict what the reactor is going to do at 10,000 hours of operation. This we must be able to do. This is one of the important things which we feel is our obligation.

Represenative HOLIFIELD. Can this sort of thing be done now, say, in an automotive engine—the airplane engine?

Dr. KRASIK. I am not familiar, sir, with those engineering problems.

Admiral RICKOVER. You don't have the many variables in the automobile engine or the aircraft engine that you have here. It is not

inherent in the thing. You never had it even back during the days of the Wright Bros.

This is the most difficult thing to explain. Perhaps I can't explain it well, but really we are dealing with entirely different phenomena. We have to set up science and technology which doesn't exist, and we are attempting to do that. That is why we have these large computation machines. By using these machines, perhaps in 3 years from now they may develop the beginning of a science of reactor technology.

I think, perhaps, with all the talk that has been going on about reactors, people have the idea that reactors are much further advanced than they are. They are not as far advanced as most of the public would think they are.

Representative HOLIFIELD. In other words, you are lacking in a lot of the basic——

Admiral RICKOVER. Basic technology.

Representative HOLIFIELD. On which to base a really sound production.

Admiral RICKOVER. That is right. We cannot do that yet. However, even though this laboratory is one of the best reactor laboratories in the United States from the standpoints of experience in designing and building reactors, and number of trained people, they cannot yet predict anything. The man who is in charge of this is telling you right now that probably he won't be able to even 3 or 4 years from now.

Representative HOLIFIELD. Then when these people come before us and predict they are going to get 6-mill or 11-mill power out of a completely undeveloped reactor, they are just guessing?

Admiral RICKOVER. You can dignify it by calling it guessing.

Mr. SIMPSON. There are two ways to design anything. One is by really knowing basically what you are doing in designing and the other is by experence and rule of thumb. With the gasoline engines they built so many of them that they built up a backlog of experience. You don't quite know why it works. In designing a circuit breaker, you don't quite know why it interrupts, but you have done so many of them that you can modify it a little bit. If you start counting the number of power reactors that have operated for long periods of time, it doesn't take very long because there are so few. So the rules of thumb, the experimental data to just give you a broad background to build on is lacking. Lacking that, you must know more of the basic science of building reactors and do more of this preliminary design work in order to do it. So the day when we have built hundreds of power reactors, a lot of people will be able to design them by rule of thumb too, but that is a long way off.

Admiral RICKOVER. We know more about what goes into a reactor design today, I think, than most automobile engine manufacturers know about the design of their engine. We have to. They have built, maybe, 100 million automobiles in this country and they have minor changes from year to year in the engines. They are not confronted with a problem of mass safety either. That is another thing. We can't just say that we will take a chance and do something. We have to be absolutely certain that this thing will work and that it will be safe.

The costs are tremendous. The man who designs a new automobile engine is not investing a hundred million dollars and it doesn't take many, many years to do it. So you have all of these imponderable

things that weigh on you here. We do not yet know why we are doing certain things in design. We were quite surprised when the prototype for the *Nautilus* worked as well as it did. We didn't know how it would work. We were very much surprised.

Representative PRICE. I was interested in your comment a moment ago on the cost per kilowatt. Representation has been made to us that at least one reactor in the power demonstration program will produce electrical energy from 12 to 14 mills or a maximum of 16 mills per kilowatt immediately upon the start of operation. Can you explain the difference in that optimism and the pessimism that you have just indicated on that point?

Admiral RICKOVER. I could only answer it this way. About 2 years ago we had a seminar on the PWR. One of the issues which came up was whether we should tell what the costs were at that time. It worked out to be 52 mills. I insisted we should say this publicly. Today it is more than 52 mills. I don't know the exact figure. It might be 65 mills.

Of course, one gets engrossed in his own work and he pretty soon begins to think he is pretty good and no one else knows anything. In order for somebody to turn out a reactor which will produce at 14 to 20 mills, he is going to have to build one a lot better than we now have or know how to build.

Representative PRICE. You know all of the reactors in this power demonstration program. Can you think of one right now which in your opinion could accomplish this?

Admiral RICKOVER. I wouldn't buy any stock in any company which guarantees to produce power at that rate. If you have any extra money, I would advise you to invest it somewhere else.

Representative PRICE. It would be a conflict of interest if we were to invest in it.

Admiral RICKOVER. I am just trying to tip you off. I would not invest money in any reactor group that claims it can do this. I think Mr. Davis, himself, has said he doesn't expect atomic power to be competitive until about 1980——

Mr. DAVIS. No! No!

Representative PRICE. It would be pretty close to being competitive. Do you even expect to do that for a while?

Admiral RICKOVER. There are a lot of other people working on this and maybe they have got some secrets or tricks. I wouldn't know how to do it. I don't know how. Maybe other people do. I obviously can't talk for them. My personal opinion is that I would be inclined to be doubtful.

Representative HOLIFIELD. Of course I have been doubtful all along on this. I haven't been carried away by any of these predictions myself.

Admiral RICKOVER. I think you could ask people, "Why are you going to do it so much cheaper than the PWR?" Maybe we could learn how to design it better, how to operate it better, and have better people doing it. We don't know how.

Representative PRICE. It could be a different system of bookkeeping.

Admiral RICKOVER. That helps too. You have another thing also. What credits do you get for plutonium? What do you charge for fuel? This came up when I was in England. They said they were

putting out very cheap power with the Calder Hall reactor. I said, "Your plant cost so much to build. It costs so much to build in the United States and it is not much off from the power of the PWR."

I said, "I am not a mathematician. I am not an economist, but it seems to me if the two plants cost about the same to put up, why do you get this vast difference in cost?" It is all Government operated. They don't have depreciation charges and so on.

Representative PRICE. What did they say it cost?

Mr. DAVIS. Calder Hall, about $45 million.

Admiral RICHOVER. $45 million, but if you took it on American costs to build, it would mean may be another 50 percent more.

Mr. DAVIS. We had some estimates made of how much we think it would cost to build a similar reactor in the United States. The best guess we have is that it would cost perhaps 50 percent more to build a Calder Hall type of reactor in the United States just because of the difference in labor rates. This would make it of the order of close to $70 million—somewhere between $60 and $70 million.

Admiral RICKOVER. You run around the same and yet they say that their power costs are about a third or fourth of ours.

Mr. DAVIS. I think you have to point out that the costs they are talking of are for Central Electricity Authority and not for the Calder Hall reactor. When they talk about 7 mills they are talking about Central Electricity Authority reactors and still on this different accounting system. They have never really said, except by indirection or just letting people believe it, that there might be 7-mill power from the Calder Hall reactor.

Admiral RICKOVER. I would say, in general, that you cannot expect anywhere in the foreseeable future, say 10 years—I don't like to go beyond 10 years—that you will have an atomic powerplant that would be competitive.

Representative PRICE. Do you think it would get close to being competitive within the next 10 years?

Admiral RICKOVER. It should, because we are learning a lot and, also, the cost of fossil fuel is going up. If there is to be a real future in atomic power, it is bound to be that way sometime. I think to sell atomic power on the basis that you are going to save money is just like the argument about putting atomic power in the Sahara Desert. I say that is a good way to build railroads. If you want to build a railroad, decide to put the plant there. Then you have to build a railroad in order to haul in the materials for the atomic powerplant. It is sort of like going around in a circle. So, one way of developing the railroad industry is to put reactors in places like the Sahara Desert.

Representative PRICE. What do you think would be the cost per kilowatt-hour of the Shippingport project.

Admiral RICKOVER. It should be considerably less, because we expect to get more power out of it, if for no other reason. We expect to get about 100,000 kilowatts out of the second core instead of 60,000 for which the first core is designed.

Representative HOLIFIELD. You could do it more quickly without this research work?

Admiral RICKOVER. We still have to do the research work, because it is a different reactor, but we have got the plant there. We just put a new core in.

Representative PRICE. What do you think the difference would be?

Admiral RICKOVER. At the time, we estimated 52 mills for the first core, I believe. We estimated 39 mills for the second one.

Mr. SIMPSON. The second core.

Admiral RICKOVER. Then we estimated for the third core that we might get down somewhere around 14 mills. That is for a new plant—building a new plant. We would use all of the lessons we have learned. Today I wouldn't be that optimistic.

Representative PRICE. That is the third core?

Admiral RICKOVER. The third core would be the first core in the second plant.

Representative PRICE. What was the figure?

Admiral RICKOVER. We gave that figure 2 years ago as 14 mills. Today I would be inclined roughly to double it.

Representative PRICE. Would that indicate this plant at Shippingport would not be as efficient as some of the claims on some other plants?

Admiral RICKOVER. Any plant you haven't built yet is always more efficient than the one you have built. That is obvious. They are all efficient when you haven't done anything on them. They are in the talking stage. Then they are all efficient. They are all cheap. They are all easy to build, and none have any problems. That is quite correct. They do not have any problems at that stage.

Representative PRICE. Have you finished, Dr. Krasik?

Dr. KRASIK. I think I have essentially concluded my remarks.

Representative HOLIFIELD. I hope you will pardon our interruptions. I think we can learn more by asking for information as we go along, and that might be the best way for us to learn.

Representative PRICE. I would say your fine presentation led to the questioning.

Representative HOLIFIELD. Mr. Chairman, I would like to have this presentation given before our full committee sometime, because this has given me a better concept of the breakdown of the time schedule than I have had before.

Representative PRICE. That is a good idea.

Mr. SIMPSON. Mr. Chairman, I would like to have Dr. Lustman, who is the manager of the metallurgy department, say a few words on the metallurgical aspects of reactor design.

STATEMENT OF DR. BENJAMIN LUSTMAN, MANAGER, METALLURGY DEPARTMENT, WESTINGHOUSE ELECTRIC CORP.

Dr. LUSTMAN. Mr. Chairman and gentlemen, as Mr. Simpson and Dr. Krasik have mentioned, once the engineering design and fabrication requirements of a specific reactor are fixed, the fuel and cladding material are then fairly well chosen. However, once this choice is made, an entire spectrum of materials development problems arise which require solution before the reactor core could be considered to be feasible. I will only give you a few of the most important type of development problems.

For example, the zirconium and zirconium alloy cladding developments—the technology which was developed in the course of the construction of the *Nautilus* core can be applied quite directly to the

construction of new submarine cores or to the A1W core of the large ship reactor.

Representative HOLIFIELD. What is the A1W?

Admiral RICKOVER. That is the aircraft-carrier project.

Representative PRICE. Let me ask you this question before we get too far along. Do you have any work here at all on the merchant-marine reactor. Do you cooperate in any way with that program?

Admiral RICKOVER. We make available the information we have learned.

Dr. LUSTMAN. In connection with his cladding problem for the PWR, pressurized-water reactor, simply a change in the design from the shape which is used for the *Nautilus* and for these other reactors required an extensive materials-development program and close cooperation an liaison between Bettis personnel, who are familiar with zirconium fabrication technology, and fabrication companies who are familiar with the fabrication of metal tubing.

On fuel materials, Bettis has taken the lead in the development of two essentially new types of fuel material. One of these is uranium oxide, which is used in the pressurized-water reactor for Shippingport. At the time uranium oxide was chosen as the preference fuel for the pressurized-water reactor, only a slight amount of laboratory-scale information was available on this material. Many of the properties which were necessary to assess the feasibility of this material as a fuel were not available. Furthermore, the technology had not been developed to permit the fabrication in shapes from uranium oxide power into production quantities.

Such basic questions as the reaction of the uranium oxide with zirconium alloy cladding, the conditions of water chemistry necessary to maintain uranium oxide in contact with water, thermal conductivity of uranium oxide—all of these questions had to be investigated and determined before the feasibility of such a material could really be supported.

In connection with a question asked by Mr. Holifield, during the course of the PWR development we did work on a similar type of alloy in the same class—uranium molybdenum alloy. The technology which was developed for this alloy is being used by the Detroit Edison group in their reactor.

Chairman DURHAM. At this point, which emits the most gamma rays—oxide or alloy?

Dr. LUSTMAN. I think it is the quantity of uranium and the amount of uranium burnt up which controls the radioactivity of the material. Large development was required for the alloys because of the lack of knowledge which existed prior to their investigation here. There were all sorts of factors—hot water corrosion resistance, thermodynamics stability of the material, specifications from purity contents, method of melting, casting, rolling, bonding with zirconium cladding—even the development of sources of metal to use as an alloy and, in addition, of suitable purity—all of these questions had to be answered. Furthermore, they had to be answered within the time period, which Dr. Krasik outlined, which is available for the development of the reactor. Certainly, many development questions have had to remain unanswered because this time period is much too short. Decisions have to be made and concurred with between Bettis per-

sonnel and Naval Reactors Branch technical personnel to permit the job to go on within the required scheduled period.

Another important field is the field of evaluation of fuel elements and fuel materials under reactor operating conditions. The greatest uncertainty in the materials field, I believe, resides in this area. This is also the widest area of research and development in reactor core materials which remains today. This uncertainty is because to a large extent there is no theoretical background which permits prediction of the effects of radiation on these fissionable materials, particularly at high levels and furthermore no background exists to guide us as to which type of experiments ought to be carried on to determine the feasibility of these materials.

Representative HOLIFIELD. You mean you don't have the knowledge and at this time you see no way of getting it?

Dr. LUSTMAN. We are getting the knowledge in the course of this development, but there is no background of metal physics or solid-state physics such as exists in other fields which gives you a lead or which tells you some things can be ignored, but other things have to be investigated more closely.

Representative HOLIFIELD. It is not a matter of making experiments along the lines that you already know. You have got to find out how to make the experiments.

Dr. LUSTMAN. How to make the experiments and what are the right experiments to make. Certainly we have made a lot of wrong experiments. We know that.

Another factor here is the very restricted amount of space which is available in reactors for doing this sort of testing, the difficulty of performing power tests in these very high radiation fields which exist in test reactors and the limitations which the very high radioactivity of the test space means after they are discharged from the reactor, the limitations of the type of examination which you can perform on these materials. All of these factors limit the rate of progress in this field.

Representative HOLIFIELD. You spoke of trouble in making the tests afterward. Is that because of the fact you have to handle them remotely?

Dr. LUSTMAN. We have to handle them remotely behind 6-foot concrete walls. You are restricted to just the simplest types of examination—things which we wouldn't even think of doing if we could phyically handle the samples ourselves.

Chairman DURHAM. Where do you do most of your metallurgical testing?

Dr. LUSTMAN. The in-power testing is done in the materials-testing reactor. A small amount is done at Hanford. Some is also done in the Canadian pile at Chalk Rover.

Chairman DURHAM. That has to be done off the base here?

Dr. LUSTMAN. That is all done off the base. Examination after they are returned from a reactor is done here at Bettis in general.

Another factor is that as the design life of advanced reactor cores is continually increased and the amounts that burn up of the fuel are increased, you get into problems at these high burn-up levels which are not in the low burn-up levels, or relatively negligible at least at the low burn-up level.

Chairman DURHAM. Which would you classify as your greater problem at the present time: control of radiation or the heat problem?

Dr. LUSTMAN. From the point of view of materials, I think the most serious problem is the effect of irradiation on the stability of the material.

Chairman DURHAM. Created by heat—would that be true?

Dr. LUSTMAN. Partly by heat, but primarily by specific effects of radiation which we do not understand at the present time.

In the course of the evaluation of the PWR fuel element, for example, almost 100 sample fuel elements were exposed in a reactor and examined after their discharge from the reactor. It would be anticipated that at least as many in-power experiments would be required for the large ship reactor and probably more to fully evaluate or to get the same stage of evaluation as we did in the PWR. Even in the PWR we simply do not have all the problems evaluated which we are sure we are going to meet in reactor operation. It is only by the operation of a reactor core that you really can evaluate the use of a new type.

Decisions have to be continually made to bypass or shortcut some sort of experiment and these decisions have to be made between Bettis and NRB technical personnel again. So we don't expect that we have made all the correct decisions.

Representative HOLIFIELD. In other words, like true scientists you would just keep on making experiments to find out more about it if you weren't stopped by the one that said we have got to get on with the job and use what we have got.

Dr. LUSTMAN. We have to say at some point, "This is far enough."

Admiral RICKOVER. We have never fixed on a reactor design yet where we had all the information we really needed. Every reactor we have built in our program has taken a calculated risk. We are doing it every day. We just don't know enough and if we waited until we got enough information we would probably never build a reactor.

Dr. LUSTMAN. As I said, we certainly don't think we have made all of the right decisions.

I think the final important area of development here at Bettis which I will just briefly mention are the development problems which arise during the course of building and assembling a reactor core.

A large number of important, unspectacular developments are necessary to make sure that the fuel elements and assemblies are fabricated under actual production conditions to tolerance levels and qualitative levels to assure efficient core performance.

Representative PRICE. Thank you very much, Dr. Lustman. Are there any questions?

Representative HOLIFIELD. I am in somewhat the position of Dr. Lustman. I don't know just exactly what question to ask.

Chairman DURHAM. The problem is no different from all the basic research in past history.

Dr. LUSTMAN. That is right. There is no physical way whereby we can reproduce these effects in fuel materials. There is no way we can simulate these effects. We have to put these things into reactors.

Representative HOLIFIELD. Are you using the Hanford reactor?

Dr. LUSTMAN. Primarily the MTR and NRX reactor at Chalf River.

Representative PRICE. What part has Bettis played in the development of zirconium?

Dr. LUSTMAN. Bettis developed the alloys which are presently being used and developed the fabrication technology. Reduction technology was developed by the Bureau of Mines primarily.

Mr. SIMPSON. Zircaloy 2, which is commonly used, was developed at Bettis. The reduction of that to being able to melt and fabricate and weld and use it in a reactor was developed here at Bettis. The creation of the materials from which to start was done by the Bureau of Mines basically. Of course, Bettis, Argonne, Battelle, and many others participated.

Chairman DURHAM. In the fabrication is there much difference in the work involved between the two?

Dr. LUSTMAN. Surprisingly enough, not very much. I think the fact that when you fabricate a metal you are able to fabricate in terms of large ingots whereas oxide is fabricated in terms of small pellets, causes a higher price for the latter type of procedure. The differences in cost are not that striking. As development continues there will be relatively small differences in price between these materials.

Representative PRICE. Thank you very much, Dr. Lustman.

Mr. SIMPSON. Mr. Chairman, in my discussion I referred to the problems of components design, components development and the materials development other than the core materials and the fuel materials.

I would like to ask the manager of the SFR, that is the submarine fleet reactor, Mr. Squire, if he would say a few words on that.

STATEMENT OF ALEXANDER SQUIRE, MANAGER, SUBMARINE FLEET REACTOR, WESTINGHOUSE ELECTRIC CORP.

Mr. SQUIRE. Mr. Chairman and gentlemen, I would like to combine two things in my discussion. One is the development of the design of the reactor plant. The second one is the specific problems on what one might call nonnuclear components. By nonnuclear components, I mean such things as the steam generator, a model of which I have over here and to which I will refer later. Mr. Simpson mentioned the basic concept of maximum reliability of components. For a reactor plant, particularly for a naval reactor plant such as the SFR, we are continually mindful of the consequences of failure of even the smallest component in a submarine plant. Since a submarine must operate submerged or maneuver in time of war we do everything in our power to develop components, to design and to manufacture components that have the maximum degree of reliability. At the same time it is necessary, as Admiral Rickover has emphasized, to utilize the available weight and space at our disposal to the maximum degree.

There is a third item of which we are cognizant as we develop new plants such as the submarine fleet reactor plants. That is, we are conscious of the fact that the Idaho plant and the *Nautilus* plant are the first of a type. That has been discussed to a certain extent here and I think it should be reemphasized that we recognize that is the model of the nuclear powerplant industry.

It would be relatively simple for us to duplicate the *Nautilus* plant for these later submarine powerplants. We think that would be wrong because we feel we can only develop knowledge by taking a fresh look at these plants and doing everything we can to develop new

concepts. When a desire for additional submarine nuclear powerplants was expressed, we got together with the naval reactors people and the Pittsburgh area office people and we attempted to set ourselves objectives to be gained. Objectives that we had not met in the *Nautilus* plant or in the Idaho plant, but which we believe to be desirable.

Some of these objectives were: better use of weight and space at our disposal; improved access to components in case they should fail or in case they should require maintenance in service; improved ability to service the components once we had got to them.

Representative HOLIFIELD. You are not talking about shifting to sodium?

Mr. SQUIRE. No sir, we are talking strictly about water-cooled plants and attempting to improve on that foundation. Our activities have been restricted to the water-cooled plants so far.

So we got together with the technical people from the Naval Reactors Branch and with their knowledge of naval requirements set ourselves a number of objectives for submarine plants—the submarine fleet reactor plants which I am using only for illustration purposes.

As we attempted to develop our ideas we constructed models of possible plants in addition to the paper studies of these plants. One of the reactor plants incorporated a steam generator of the type I am showing you—this model standing here in this room. The steam generator is, of course, the main vehicle for transferring heat from the reactor plant to what we call the secondary plant, the turbine plant. This new steam generator offered real promise for improved space utilization. However, a steam generator of this type to perform in accordance with our operational requirements had not been built before.

The Naval Reactors Branch people and we, jointly, went to the manufacturers of components of this type and discussed with them the feasibility of the manufacture of the steam generator.

Representative HOLIFIELD. You are talking about changing from the *Nautilus* type to an improved type?

Mr. SQUIRE. Yes, using in general the same principle. The manufacturers of equipment of this sort saw no reason why such a unit could not be built. We decided it was worth a trial. It had not been done before, but it was worth trying out for the possible gains to be made in advancing the design of reactor plants.

Representative HOLIFIELD. How does the model compare in size?

Mr. SQUIRE. This, sir, is one-quarter of the size. That is for this particular plant. A plant of larger capacity, obviously, would require a larger steam generator.

As I said, we decided to go ahead and make this. To make a long story short, we had to make dozens of forgings before we could get forgings of adequate quality to put in these units.

There is an obvious question as to why we had so much difficulty getting these forgings when people have been making large forgings for many years. This brings us to another basic point in component design and construction. In naval powerplants or in any reactor plant, for that matter, one of our requirements is that we be able to heat up and cool down these plants rapidly. The obvious reason for this is that it may be necessary for these plants to get up a head of steam and get out of a given port or a given location on very short notice.

In order to minimize the problems associated with rapid heatup and in order to minimize the thermal stresses that are set up in components like this, it is necessary to use as thin sections as is consistent with reliability of the components. In order to use the thinnest sections possible, we have got to get the soundest material possible. We did not set ourselves goals that people believed were unattainable, but we set ourselves goals that we believed we could meet, but not very easily.

We finally obtained enough forgings to take care of this program, but in so doing actually the forging technology had to be advanced. Melting practices had to be improved by the forging suppliers and so one might say that there has been a broad gain by standards set up at Bethlehem and Midvale Co., just in building these units.

Chairman DURHAM. What did they do to it?

Mr. SQUIRE. It was more a question of controlling the melting practice more closely, limiting the time that the material was kept at temperature, controlling the additions that they used for the refinement of the grains in the material, and controlling the forging processes more closely than they normally do. There has been no basic change in composition.

Chairman DURHAM. No change in composition of the alloy?

Mr. SQUIRE. No basic change in composition of the alloy although at one stage in the game, the companies threw up their hands.

Admiral RICKOVER. Mr. Durham, on surface ships with which you are familiar, like the one you were on during World War I, we get one-tenth of 1 percent of sea water through our condensers in what we consider a normally tight condenser. With our boiler water compounds we can blow down and get rid of it. With stainless steel you can't do that. With stainless steel, if you get a few parts per million—it is just fantastically small amounts that will cause cracking in tubes.

As Mr. Squire said, since the whole source of your water—all your fresh water on naval vessels comes originally from salt water, it is very difficult to keep minute traces out and yet it is the minute traces that concern us and cause failure. We do get around it by having suitable boiler water treatment and renewing water frequently.

Mr. SQUIRE. There are several ways of preventing failure of boiler tubes. One is complete removal of the chlorides and oxygen or any other chemical that might influence failure.

There has been a major effort put on this by all of the manufacturers of steam generators in this business. The Naval Reactors Branch have been working with the boiler manufacturers.

I just want to leave this thought with you before I terminate. All the problems are not associated with cores. There are many, many problems associated with the more common materials and actually these problems seem to hold us up just as much as such things as uranium.

Mr. SIMPSON. We have now covered the physics, the metallurgy as applied to cores, the materials as applied to the other components and a typical design problem of the nonnuclear components.

I would like now to ask Dr. Esselman if he would take a few minutes to describe the advanced development work which we are doing in reactor plant design concepts and in looking at some of the other possibilities than the plants which are actually built. Dr. Esselman spent 2 years out in Idaho in actual "rubbing shoulders" work with radioactivity. He was in charge of the technical operation of the naval reactor facility there. He has known radioactive contamination firsthand and also the maintenance problems. He heads up our development here with a real down-to-earth background of the practical aspects of reactor design and operation.

Representative PRICE. Dr. Esselman.

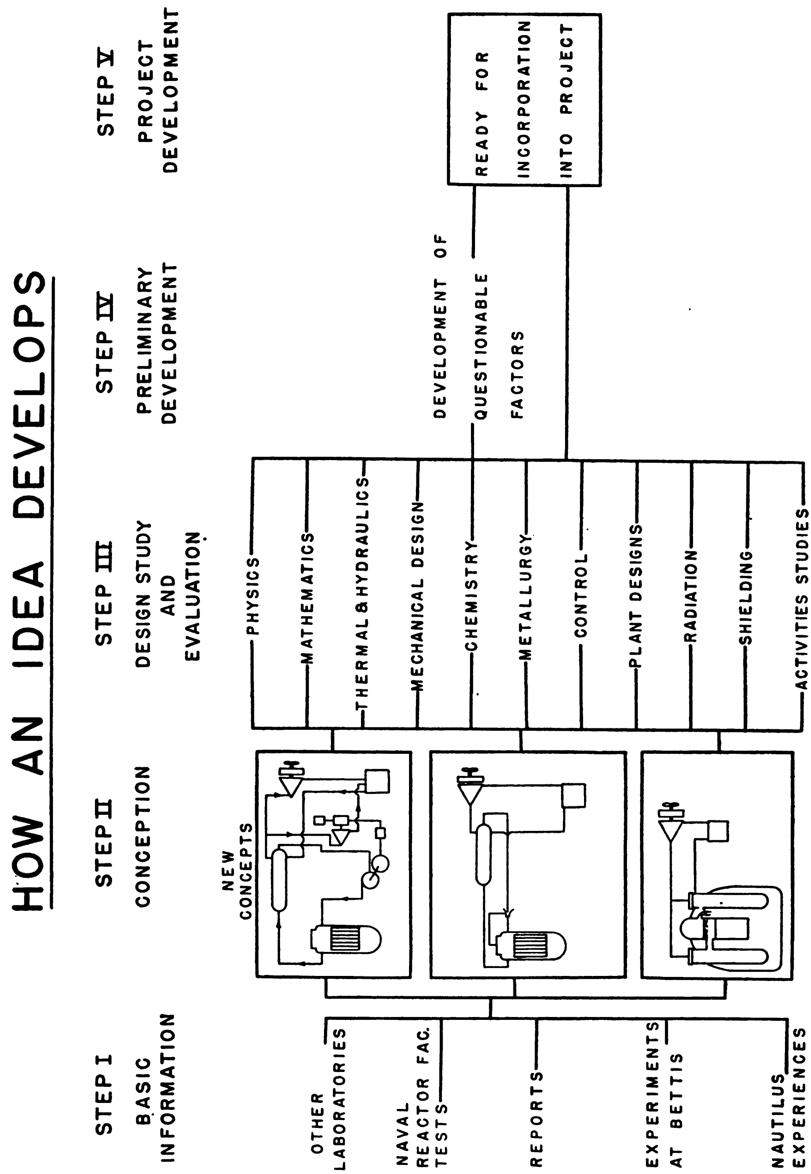
STATEMENT OF DR. WALTER ESSELMAN, MANAGER, ADVANCED DEVELOPMENT GROUP, WESTINGHOUSE ELECTRIC CORP.

Dr. ESSELMAN. Mr. Chairman, the topic which I wish to cover is the procedure for developing an idea before it is incorporated into a project. Many ideas are always being suggested and it is necessary for someone to determine whether it is feasible, desirable, and worthy of being incorporated in a project at Bettis. This work is done by the advanced development group.

The work of the advanced development group is primarily concerned with applications for naval reactors. However, the concepts which are considered worthy of consideration would apply to all types of reactors. This point is illustrated by the objectives of this group in that their studies are all based upon trying to achieve reduced cost of plants and cores, reduced weight per shaft horsepower and, third, maintenance and improvement of the reliability of the nuclear reactor plant.

The first of these—at reduced cost—naturally is of value to all types of nuclear reactors. Secondly, to reduce the weight per shaft horsepower also reflects in the plant cost and usually if a plant is lighter, it will cost less. The third one which is the reliability objective, I have stated as "maintaining reliability" because I do not wish to imply that we are not pleased with the reliability of the powerplants which we have built, but rather any new idea which we would conceive or evaluate should not jeopardize the record which has been made to date.

In order to illustrate the steps which are taken prior to the use of any idea, your attention is invited to this chart. This chart indicates how an idea is developed.



Step 1 is the need for basic information. Basic information is not much stimulus for coming up with new concepts and if you come up with a new concept, you have no information or data with which to evaluate. This information is obtained from other laboratories in the case of plants which are different types than we are building here.

The second one of our great sources for information is the naval reactor facility at Idaho. The third is various reports. The fourth that I have indicated are experiments at Bettis and the fifth is experience on the *Nautilus*.

In order to illustrate a typical example of where information is of great value, I would like to take the field of thermal hydraulics. During design stages on core No. 1, very little was known about the amount of heat that could be passed through a surface—metal surface without causing melt down. A laboratory was set up at Bettis to get experimental points under various values of waterflow, various values of temperature and today we believe we know quite accurately what the burnout points or melt-down points are on heat transfer surfaces. There are many other facets of hydraulic problems of which very little is known. Today we feel we have solved some of these problems. This field is very important in that the power output for any particular core is governed by the amount of heat we can pass through this surface.

We are continuing experiments in this thermal hydraulic laboratory in this field of transient heat flow. At the present time output on several of our cores is limited because of the transient that occurs if the pump would stop. To date no laboratory has done any experiment on transient heat transfer which we can apply to designs which we are making on water-cooled reactors.

The data that we obtain from the naval reactor facility is also important. In fact, it is the only power reactor that we have available to obtain information on reactor operation. At that facility we are continually checking on the activity buildup in loops and performing other chemistry tests. Experiments are being performed on core lifetimes. Unless you have a power facility you cannot really determine the practicality of these principles and you cannot really determine what the life of a core would be.

We are also doing experiments in heat transfer.

When we get this information the next step is the conception of new ideas. Actually the conception of new ideas is not a difficult part of this process. The difficult part is to evaluate the ideas that you have to determine which are good ones and which are to be followed. Many ideas are available for evaluation. The thing that is difficult is to limit the number of studies we want to make by this group to a number which can be accommodated with the few people that we have. At some time we combine several ideas or a number of ideas and discuss the possibility of starting a design study on a typical type of ship. We discuss with the AEC Naval Reactors Branch. We decide, for example, that the study should be conducted for a submarine or some other type of surface vessel.

We are making at this point a very practical study of a design concept. We are making a desirability study of a plant for a particular ship. The third step then is the design study and evaluation. The number of technologies that are involved are indicated. Actually there is probably only one of these various technologists performing this study so this is a relatively small organization. The more scientific aspects require the work of physicists, mathematicians, and metallurgists. The engineering aspects are covered by thermodynamicists and thermal hydraulic mechanical design, control engineering and you see here things such as plant designs. Actually in the study we will make an actual plant layout.

These studies are sometimes affected by things in the engine room which are quite remote from the actual reactor which we are design-

ing. Radiation studies are made in various plants and are compared based upon irradiation to the crew in this ship. If we were making a general study and were not confining this to a particular type vessel, the radiation problem would change, and this changes the concept of what we might build considerably.

At the end of this study we now have established that a particular concept is desirable. I hesitate to use the word "feasible" because at this point what we have come up with is a knowledge that a certain type plant would have a certain weight per shaft horsepower. It will have certain operational characteristics, but there are usually a number of problems that require development. The development of these is then undertaken on a small scale.

Step 4 can be undertaken on a small scale to determine whether some of these features that we consider problems really exist. Finally after we have done this it is ready for incorporation into a project. If we have enough knowledge of the plant which we are designing, for example, if it was a water-cooled plant, we would not have to do too much development in this step 4. It could go directly into a project.

I do not wish to indicate that the development is anywhere nearly completed at this point. It is really only beginning. What we have established to the point of incorporation in a project is that an idea will probably be feasible when the development in the project is completed. We have merely sifted the various ideas which were presented to those which are probably capable of solution and should be incorporated in a reactor plant.

Representative PRICE. May the committee have a copy of those charts for its record?

Dr. ESSELMAN. Certainly.

In conclusion I wish to state that we are looking at various types of reactors. The advanced development group's thoughts are quite broad in scope. We are looking at improvement to water-cooled reactors as well as other types of reactors. I think the setup which we have whereby the various people in the study group are so closely related to the people in the projects results in a very practical approach. The fact that the people in the study group realize that the ideas which they are trying to sell will very soon be in a project forces the practical approach. Also the people in the group are the ones who have had experience with the design of core 1 or the mark 1 plants or with the operation of a plant so that the personnel we have will certainly take the practical approach in any design study.

Representative PRICE. Thank you very much, Dr. Esselman, I see it is close to 1 o'clock. I think the committee should recess and if there is any further presentation we can return here this afternoon.

(Whereupon at 1 p. m. the subcommittee recessed.)

AFTERNOON SESSION

The Subcommittee on Research and Development resumed its meeting at 4 p. m. in conference room No. 2, Westinghouse Bettis plant, Pittsburgh, Pa., Hon. Melvin Price (chairman of the subcommittee) presiding.

Present were Representatives Carl T. Durham (chairman of the full committee), Chet Holifield, and Melvin Price (presiding).

Staff members present: James T. Ramey, executive director and George E. Brown, Jr.

Representatives of the Atomic Energy Commission: Kenneth E. Fields, General Manager; W. Kenneth Davis, Director, Division of Reactor Development; Rear Adm. H. G. Rickover, Chief, Naval Reactors Branch, and Comdr. V. A. Lascara, Naval Reactors Branch; John M. Bodley, Special Assistant to Commissioners Libby and Vance; Bryan F. LaPlante, Congressional Liaison Officer; L. D. Geiger, Manager, Pittsburgh Area Office, and Comdr. R. V. Laney, Assistant to Pittsburgh Area Manager (Reactors).

Representative PRICE. The subcommittee will be in order.

I think the committee may want to discuss some of the things that we saw here this morning and get the reactions to the presentations that were made this morning. We would also like to know from the local people here, representing the AEC, what they find their problems to be—matters of supply—matter of funds.

I think the members of the committee all agree with me that this is probably one of the most important projects to our national defense of any that we have in the AEC program. I think they would also agree with me that the AEC and Navy both should give it the fullest possible importance and do everything they possibly can do to promote this project and to expedite the various programs.

If someone would like to make a presenation on behalf of the Atomic Energy Commission, this committee would certainly be happy to have your presentation.

STATEMENT OF KENNETH E. FIELDS, GENERAL MANAGER; W. KENNETH DAVIS, DIRECTOR, DIVISION OF REACTOR DEVELOPMENT, AND ADM. H. G. RICKOVER, CHIEF, NAVAL REACTORS BRANCH, ATOMIC ENERGY COMMISSION

Mr. FIELDS. I didn't have any presentation to make from our side on this endeavor. I would definitely second what you have said so very strongly that this is one of the most important installations we have. I have been impressed with it ever since my first association with it in the sense that it is a clear illustration of what is necessary, I believe, in a number of areas in our reactor program—not just here, but elsewhere too. You have got to go all the way through a reactor program to come out with effective reactors. You can't just build the end product. There is a great deal of research and development in material, physics, and metallurgy that must be done. From what I have been able to make out you can do everything with respect to reactors here that needs to be done with one exception. That is the chemical reprocessing of fuels. You don't attack that problem here. Otherwise it is a complete system, as far as I can see, in propulsion plant development.

Chairman DURHAM. Is this the only place that we have where we can build a reactor from the ground up?

Mr. FIELDS. Knolls can do this and I would think——

Mr. DAVIS. Argonne.

Mr. FIELDS. Argonne and Oak Ridge not quite to that extent, but they are building reactors or getting to it. They haven't built them as big as the PWR.

Chairman DURHAM. I am talking about something of the size of the PWR.

Mr. FIELDS. I think it is a very complete research and development installation in that it has the scientific resources and research sort of efforts that go on here and are necessary to develop a particular concept of reactor. Here the work you are doing in the pressurized water reactors will be used very widely in the naval field, but it will also be extremely useful in a civilian power field. You have the general key coming from this. I believe parts of the Consolidated Edison central station reactor very definitely flow from this.

As far as I know we have given this every help that it needs as well as encouragement. We are very strongly of the belief that there is a great future for this kind of a reactor both for naval use and for civilian power use. Although it is useful in naval propulsion it is the same information you have to have for civilian power reactors. This material you have out here would behave the same whether it is a military reactor or a civilian reactor. So there are great benefits to a civilian program that will flow from the military research that is being done. There has been a great deal of declassification that has opened up much of this information to the civilian program.

Representative PRICE. How extensively is this project declassified?

Mr. FIELDS. You had better answer that, Admiral Rickover. I am under the impression that practically everything on the PWR is now declassified.

Admiral RICKOVER. The PWR is completely declassified. We have actually gone much further than that. We have taken practically all the technical information from the naval programs and have declassified it also. We have set up a distinction between the technology as such, as opposed to specific design and dimensional characteristics. We have decided and the Commission has backed us that pure technology shall be declassified. We have made that unclassified information so that anybody in this country who wants to build a pressurized water reactor can get all of the technology. As far as giving our specific dimensions for a submarine reactor, we are keeping that classified.

Representative HOLIFIELD. What about specific cores for the PWR and all of these—your techniques for making these fuel rods?

Admiral RICKOVER. Let me put it this way. There is not a single thing in the PWR which is now classified. I don't know of a single aspect of the PWR, whether it is technology or whether it is design, or construction or dimensions that is any longer classified.

There are sometimes arguments as to whether new reactor ideas should be made public. You know the theory in the reactor game that everything that is born is always born with a restricted data stamp on it. We are pretty much disregarding that with the new PWR cores that we are developing. I am sure your committee would want it that way. We feel that for civilian reactors there is no reason why we should go back to the old system where scientists and engineers could not talk with each other. We think it is of much greater advantage to the United States to get this information out into the people's hands. I am talking now as a military man. I think it would hurt this country not to do it.

Chairman DURHAM. Does that include all metallurgy also?

Admiral RICKOVER. It is all-inclusive for the PWR, Mr. Durham. It includes the technology, the physics, the fabrication techniques—anything at all. There is nothing in the PWR we classify. It is just the same as if you were going to buy a toaster, a phonograph, or something like that.

Mr. FIELDS. I would like to footnote a couple of things that occurred to me while we were listening to these presentations and in going through here today.

At some point in the briefing there was a discussion of the second submarine core. I am not sure it was the second core actually. It was a subsequent core where we developed a longer life and the fact that the idea for this concept came in 1952. I believe that was the date the man gave. Here it is 5 years later. It was first thought of 5 years ago. Let me just put that one fact down. In the second one they brought out these different materials.

The reason I wanted to sort of footnote these is because these are the successes in development and achievements that let this go forward, but they are really only the first steps. There is a long way down the road to go yet even in this particular area. I believe we make the mistake too often when we have gone through and developed something like the PWR of thinking that is the end of the road when it is really only the first step for the pressurized water reactor. There are any number of years when this same group here should continue this development of new types of cores and modifications of the PWR itself to improve the power levels and the performance of that particular reactor. That is the way you are really going to go forward in this business.

Representative HOLIFIELD. I am glad you brought that up. First let me ask you when the PWR will be finished? That is in the fall, isn't it?

Mr. FIELDS. The last I heard is late in the year.

Admiral RICKOVER. We have hopes that it will go critical late this year. It may not be this year and it may not be until some time early next year. We don't know. We are trying to get a reading on it.

There are two principles we follow. One is that under no circumstances should we go ahead and make an announcement about something here, advertise it and not have it come through. Second, I don't think we should do anything—take any shortcuts which would jeopardize the successful operation. We have a large amount of instrumentation in this core which you don't need in an ordinary reactor. We are doing it for one reason, because we conceive it was the intent of the Atomic Energy Commission and the Congress for us to learn design lessons for future reactors from this core. That is one of the most important things. We don't want to take any shortcuts which will stop us from learning. The job is so much vaster than any of us originally thought. We all fell down on the time estimate. So it may take a litle longer than we originally thought.

I think you are finding this is true of all reactor programs. I think you have to realize that we are just today beginning to get a glimmer of what a vast and difficult thing a power reactor is to design and build.

Representative PRICE. How much of the physical part of the reactor is manufactured outside of your own installation?

Admiral RICKOVER. About the only thing we have made here is the core. That is our policy. Make the first core of its type in the laboratory because it is developmental. Practically everything else is made outside and nearly all on competitive bidding.

Representative PRICE. Have any cores been made outside? I am not talking about power reactors.

Admiral RICKOVER. May I answer that question in a different way? Let me rephrase your question if you will permit me to do so. What we have done is to establish an industry to make parts both for the naval reactor program and the PWR. Can I answer it that way because I think it will bring it out better?

When we strted out, of course, we had only one core for the Mark 1, but we realized if we were going to have a nuclear Navy, we would have to build up a nuclear industry. An industry for nuclear power consists of two parts. First you have to get certain raw materials. The basic raw material is uranium. That is supplied to us by the AEC so we dont' have that to worry about. The next thing is material such as zirconium. When we started out we made it at Government laboratories such as the Bureau of Mines Laboratory at Albany, Oreg., and by Government subsidization of Foote Mineral Co. and the Carborundum Co.

Then about a year and a half ago we went out and made contracts with three large companies for zirconium. This was all on a competitive basis, lump sum. One of the contracts was with the Carborundum Co. which was already in the business. Another company, National Distillers, is setting up a plant. The National Research Corp. is also building a zirconium plant.

We made contracts with these companies with funds supplied from Navy shipbuilding appropriations to get about 2 million pounds of zirconium a year for 5 years. At the end of that time it will be a completely open competitive market. These companies will put in enough additional capacity to take care of civilian reactor requirements also.

I would like to say that with the steps we have taken zirconium will be in open supply by a competitive industry.

Mr. FIELDS. Do you have any figures you could quote with respect to price before and after?

Admiral RICKOVER. I will give you some figures. When we started several years ago we were paying $300 a pound for zirconium sponge. That was the price when we first started. Next we made a contract with the Foote Mineral Co. What did that run to?

Commander LASCARA. It cost us about $250 a pound and we furnished the feed material.

Admiral RICKOVER. Mind you, that was the first contract.

Representative PRICE. With what company?

Admiral RICKOVER. The Foote Mineral Co. near Philadelphia. I think the total contract was about $2.5 million.

The next contract we made was with the Carborundum Co. for quantities which totaled up to about 30,000 pounds a month and we got that for about $13.20 a pound for sponge, roughly. So we have gone down from $300 to $250 to $13.20 a pound. The contract which we made this past year with Carborundum was for $7.72 a pound instead of $13.20 and the other contracts were even lower.

Mr. FIELDS. How long a term contract?

Admiral RICKOVER. These are 5-year contracts. These contracts are to the great advantage of the Government.

Representative PRICE. How much zirconium is being produced a year?

Admiral RICKOVER. We will get roughly out of all of these contracts about 2 million pounds a year, which we will need for the naval program and for PWR cores.

Representative PRICE. What is the potential demand for zirconium in the future?

Admiral RICKOVER. We figure with the expanded capacity that these people are putting in they will be able to take care of General Electric Co. and Babcock & Wilcox and others who are building commercial reactors. They are putting in additional capacity. This is a new industry, but it should follow the path of other industry. We feel the Government can get out of the zirconium business at the end of the 5-year period and buy it on a normal, competitive basis.

However, the General Accounting Office has just come up with the thought the Commission should not contract for raw materials in this manner.

Representative HOLIFIELD. I was going to ask if the other contract was a Navy or a commission contract.

Admiral RICKOVER. The Navy transferred funds to the AEC. The Commission handled it because all of the know-how for handling this material is in the Commission so we were faced with the proposition of setting up another Government agency——

Mr. FIELDS. There was another reason for procuring zirconium and beryllium in this way. We didn't see why we should have separate agencies trying to develop this industry.

Representative HOLIFIELD. I heartily agree with you.

Mr. FIELDS. We all agreed one agency should do it and I think it came out we felt we should do it and they agreed with us.

Admiral RICKOVER. Under no circumstances should any other Government agency get into this field as long as it is being handled properly and efficiently by the AEC. It so happens that the Commission has designated Mr. Geiger, the manager of the Pittsburgh area office, to handle all zirconium procurement. We deal through this one source and in this way we are able to get an advantage in price.

There is another major advantage. Most of the technical know-how on zirconium is located right in this Bettis plant. We have the people here who are qualified to instruct all of the new people how to do it and to do it efficiently and properly.

The Commission may need the help of Congress in connection with our present method of zirconium procurement.

Mr. FIELDS. What kind of an obligation do we have to make against that contract?

Mr. DAVIS. The terms of our contract?

Mr. FIELDS. In terms of contract you obligate money—do you obligate it so that if we cancel a contract, we give them some kind of cancellation determination?

Admiral RICKOVER. Commander Lascara, you are familiar with the details of that.

Commander LASCARA. The Navy has put up $7.5 million for cancellation charges for its share of the zirconium production over a 5-year period. I think the AEC has about $1.6 million in cancella-

tion charges for its share. During the 5-year period, if the contracts are canceled, say, at the end of the first year of the contract we are obligated to pay these companies a fixed amount for cancellation. I don't know what the exact dollar amount of the cancellation charge is.

Mr. GEIGER. The contracts are written so that if the Government were to cancel them before they start production or during the year or year and a half required to build the plant and get into production, we have certain obligations to pay up to a portion of their capital investment.

Chairman DURHAM. Up to 5 years?

Mr. GEIGER. No, sir; this is until the time they begin production. From the time they actually begin production, there are smaller cancellation charges. They are relatively small.

Mr. FIELDS. Going down to zero.

Mr. GEIGER. By the end of the 5-year period, of course, it is zero.

Representative PRICE. How many companies are in this business?

Commander LASCARA. There are three long-term contracts. We have a fourth company which has a short term contract.

Mr. GEIGER. Carborundum Co., National Distillers Corp., National Research Metals.

Admiral RICKOVER. National Research Corp.

Mr. GEIGER. NRC Metals is a wholly owned subsidiary of National Research Corp.

Mr. DAVIS. Only half.

Mr. GEIGER. Fifty percent of it was recently purchased by Columbia Southern, a subsidiary of Pittsburgh Plate Glass.

Representative PRICE. What is the fourth?

Admiral RICKOVER. Wah Chang. They are running the Bureau of Mines zirconium plant at Albany, Oreg. They have a lot to do with titanium. They have leased the Bureau of Mines—the Government-owned plant at Albany, Oreg. and are making zirconium for us now.

At any rate I would like to assure you that we have gotten a much better price, this way of doing it, for the Government than we could have done any other way. I hope the joint congressional committee backs this idea of doing it in this manner.

Chairman DURHAM. Is Wah Chang operating offshore of the continental United States?

Mr. GEIGER. No; Wah Chang is a domestic company.

Chairman DURHAM. He is all over the world.

Mr. GEIGER. It is an American company.

Chairman DURHAM. An American-Chinese company. He is the man who got a lot of tungsten out of China for us during the war.

Mr. GEIGER. He has brought in many minerals from many countries.

Chairman DURHAM. He is down in Brazil at the present time. Can you give us the contract price for each company?

Admiral RICKOVER. We can supply it for the record.

(The information referred to follows:)

National Distillers, $4.53 per pound; NRC Metals, $6.50 per pound; Carborundum Metals (Akron, Ohio), $11.42 per pound; Carborundum Metals (Parkersburg, W. Va.), $7.72 per pound; Wah Chang, $9.07 per pound (Government-owned facilities).

Chairman DURHAM. You mentioned a price of $13.

Mr. GEIGER. I can give you the price.

Chairman DURHAM. How long does that contract run at $13?

Mr. GEIGER. That original Carborundum contract runs until December 1958. Since they started production we have negotiated 3 annual price redeterminations bringing the price down to where, today, we are paying $11.42 a pound.

Chairman DURHAM. There is a renegotiation clause?

Mr. GEIGER. We renegotiate a new price once a year prospectively under that contract.

Representative PRICE. Do all of these contracts have renegotiation clauses?

Mr. GEIGER. The new contracts were all competitively bid contracts.

Representative PRICE. What was the lowest bid that you had?

Mr. GEIGER. The lowest bid is the one submitted by National Distillers of $4.53 a pound.

Representative PRICE. How many pounds do they supply?

Mr. GEIGER. A million pounds a year.

Mr. RAMEY. That is your largest contract.

Mr. GEIGER. That is the largest contract.

Chairman DURHAM. Are they producing?

Mr. GEIGER. No; they are not yet in production. They are building a plant at Ashtabula, Ohio. They were scheduled to be in production July of this year, but they are going to be late.

Chairman DURHAM. Where did they get their experience?

Mr. GEIGER. Several years ago National Distillers decided to diversify into the chemical field, and they set up a chemistry division. They are in the petrochemical field and they are also large producers of sodium metal. It was their interest in sodium metal which led them into the titanium and zirconium fields.

Chairman DURHAM. What was Wah Chang's bid? Do you remember?

Mr. GEIGER. Wah Chang is producing zirconium in a Government-owned plant. They are operating a Government-owned plant and selling zirconium to us for $9.13 a pound.

Representative PRICE. What makes the big difference in the prices? Was there no experience to begin with? Is it because the earlier process was not quite as efficient?

Mr. GEIGER. The biggest single factor is the rate of production. Today we are paying $9.13 a pound for material produced in a Government-owned plant where there is no amortization. We are paying $11.42 a pound in a plant that can produce at a rate of 300,000 pounds a year. The lower prices are based on production rates in excess of a million pounds a year.

Mr. RAMEY. Is there no difference in processing?

Mr. GEIGER. There are improved processes, but I think the production rate has a lot to do with the prices. If the production rate goes up, the price goes down.

Representative HOLIFIELD. I think we have got off the track a bit from our first line of questioning, although I am very much interested in this. I had asked a question as to when we would be through with the PWR. The reason I asked that question was because I wanted to see what kind of a breakdown your organization, Admiral Rickover, has in naval work that they are doing on the submarines and the work that they are doing on the PWR. Are you doing work on both of those projects?

Admiral RICKOVER. Yes.

Representative HOLIFIELD. You gave us some figures once before on the number of people you have in your organization. How much of that organization is devoted to the PWR and how much is devoted to the naval portion? Can you differentiate?

Admiral RICKOVER. I will try to give you some rough figures. Of course most of the developmental work in the PWR is finished. It has been for some time in the construction stage. Today the great majority of the work is in the followup of components and seeing that the installation gets done. I would say that about 20 to 25 percent of the effort of my organization is now devoted to the PWR. However, you must bear in mind that the technology in the PWR and the things that we do—what we learn on one reactor, we are learning for the others. That, of course, is the great advantage for having done the PWR here at Bettis and one of the reasons why the Commission assigned it here because it uses the same technology at the naval plant. For instance, a great deal we have learned on the PWR we are incorporating in the large ship reactor project. A great deal that we learned in naval reactors we have incorporated in the PWR. So even though we may spend 25 percent of our effort on it, on the other hand if we weren't doing it on the PWR, we would probably have to use about 12½ percent of the effort on naval cores anyway.

Representative HOLIFIELD. In the main you have put your best developmental people into the naval portion of the program?

Admiral RICKOVER. We use the same quality people on the naval program and on the PWR. We are starting a second core for the PWR. We have taken some of the developmental people, both here and in the Naval Reactors Branch, off the PWR and we are putting them on the other work because we no longer need as many on the new PWR core as we did on the original one.

Representative HOLIFIELD. As far as your organization is concerned, what will you be working in when you finish the PWR? You have a pretty good organization put together. Are you going to be able to absorb them in this big naval aircraft carrier and the submarine projects? Would you be able to take an additional project?

Admiral RICKOVER. You are saying, "When a man is already carrying a heavy load, could you add another straw before you break his back?" Sure, we could take on another project.

Representative HOLIFIELD. No, that isn't what I mean. If you have 25 percent of your people in the PWR, are you going to move them over into the naval program? Are you going to retain them or are they going to be dispersed throughout the country?

Admiral RICKOVER. No, they are not going to be dispersed. There is so much to be done that you can always find use for them. You were talking about another project. You asked me the last time I testified before your committee in Washington whether we could take another program. I said, "Yes," because I would just make out. I would train more people. You just keep on. That is all.

Representative HOLIFIELD. Do most of your finances now on the naval part of your program come from the AEC or does it come from the Navy?

Admiral RICKOVER. The finances are split two ways according to an agreement the Department of Defense made with the AEC. The research and development part is paid for by the AEC. The production part is paid for by the Navy. Any research and development on the steam part of the plant is paid for by the Navy, and construction of nuclear ships is paid for by the Navy. I think I can illustrate that better by giving you an example of how a big project works.

We will take the large ship reactor project. The AEC finances all of the research and development for the first plant. They also finance the construction of the prototype at Arco, and they finance the operation of the prototype. The Navy finances the entire cost of the ship plus the cost of the reactors in the ship. That is the general line of division between the AEC and the Navy. The AEC finances research and development plus prototype. The Navy pays for the ship and the cores that go into the ship.

Representative HOLIFIELD. Mr. Fields, how much are you using in the way of AEC funds to sustain this operation of Admiral Rickover's here?

Mr. FIELDS. I think you had better answer that, Rick.

Admiral RICKOVER. I will talk about fiscal year 1958. The AEC is putting up about $86 million for research and development.

Mr. FIELDS. $72 in fiscal 1957. That is operating funds.

Admiral RICKOVER. $86 million in fiscal year 1958. That does not include construction funds from the AEC.

Commander LASCARA. That is right.

Admiral RICKOVER. $25 million for construction funds—something like that. I don't know the exact amount.

Mr. RAMEY. How many people do you have?

Admiral RICKOVER. At Bettis we have about 5,300 people of whom about 1,300 are scientists and engineers.

Mr. FIELDS. This entire budget isn't spent here.

Admiral RICKOVER. It is spent here, at General Electric, Combustion Engineering, and many other places.

Chairman DURHAM. Does that $86 million mean completion of all the submarines that we have authorized so far?

Admiral RICKOVER. No, sir; that is not for actual construction of submarines. That is for research and development on naval nuclear propulsion—for the entire naval program.

Chairman DURHAM. I know that.

Admiral RICKOVER. You mean when we finish up with the $86 million?

Chairman DURHAM. Yes.

Admiral RICKOVER. No, sir. There will be continuous research and development in the coming years too.

Chairman DURHAM. In other words, you must expect research and development funds if you are not to continue building copies of the *Nautilus* type submarine reactor?

Admiral RICKOVER. We are not building any more *Nautilus* type.

Chairman DURHAM. I know. I am talking about whether you expect research and development funds from the AEC to continue the program on a research basis regardless of how many submarine reactors you build.

Admiral RICKOVER. Yes. If the Congress wants us to have improved reactors and wants us to learn, we have got to do this. This is the only way we know how to do it.

Representative PRICE. I want to get back to what Mr. Holifield started in his questions. Since the beginning of the Shippingport project which is when you are going through the peak years, what percentage of your work went into the project?

Admiral RICKOVER. You are talking about manpower?

Representative PRICE. Manpower and the efforts of your organization.

Admiral RICKOVER. At the peak it was at least 30 or 40 percent or perhaps more of this laboratory's efforts. I think it took about 300 scientists and engineers together with the necessary supporting personnel a total of about 5 years to do that job. That was a considerable effort. That same percentage applied in my headquarters organization in Washington. We actually gave the PWR the highest priority—even over the Navy program.

Representative PRICE. About 300 scientists and engineers during that period working exclusively on the PWR?

Admiral RICKOVER. That is right here at Bettis. This doesn't include people in the other organizations that contributed.

Representative PRICE. You are talking about the Bettis organization.

Admiral RICKOVER. That is about correct, isn't it?

Mr. GEIGER. I think that is right.

Representative HOLIFIELD. What are your general thoughts, Mr. Fields, for keeping this organization busy?

Mr. FIELDS. I don't think we have a problem in keeping them busy, Mr. Holifield. In a way this is the point I was trying to make. We have a tendency too often to think once one of these reactors go critical, that you have come to the end of the job, but you haven't at all. You have a tremendous payoff. Another 5 or 10 years in development at least—and probably more—in this field in extending the life of these machines, improving the cores, possibly modifications will come along in components, will simplify it, make it better.

Representative HOLIFIELD. How about starting from scratch and building on the basis of that knowledge—building another reactor? Is there a payoff there?

Mr. FIELDS. There could be, but——

Representative HOLIFIELD. In the meantime you keep on getting operating experience and you are improving.

Mr. FIELDS. You don't get operating experience by just operating a core longer than its life and replacing that same core in there. You need an improved type of core if you are going to progress down the line.

Admiral RICKOVER. Let me try to answer this question. I will give you an example.

Mr. FIELDS. O. K., but let me just say again that I think there is a tremendous amount of improvement possible in all of these things we have started. The PWR I would predict would be here for 15 years.

Admiral RICKOVER. Take the PWR. We will install the first core in it, and it will start operating toward the end of this year or the early part of next year. That core may last 3 or 4 years. In the

meantime we are designing another core. You might say, "Why don't we start and build another PWR reactor?" I wouldn't do that. I don't think there is enough gained.

Representative HOLIFIELD. That is what I am trying to get at.

Admiral RICKOVER. I wouldn't do that. I know this is contrary to what a lot of other people are saying. To go ahead and build a brand new pressurized water reactor and start from scratch will take 5 years at least, and the people who are going to design and build it are going to come around here and copy what they have here. So what have you got at the end of 5 years? You have got something that is already obsolete. As General Fields has said, we think it is much cheaper to design improved cores and use them in the present PWR plant.

Representative HOLIFIELD. Pull the old core out and put that in?

Admiral RICKOVER. When the first core is used up, install the second one; meanwhile start the design of a third new and improved type core. That would be the cheapest and best and quickest way of learning.

Mr. DAVIS. I think there is one more thing. It seems to me you have two problems in trying to develop something like the pressurized water reactor to the point where it is going to be pretty useful. One is to get the cost of the plant itself, which is very high in terms of dollars per kilowatt, down. The other is to get the cost of the fuel down. These are the two main components of the cost that are very high today.

You will do this in somewhat different ways. I think we have talked quite a bit about how we can cut the cost of a particular core and also extend its life. If you can do both of those rather successfully, you can cut the fuel costs into a fraction of what it is for the first core. You do this by putting in one core, then building an improved core and another improved core. You can put these all into the same reactor.

The cost of the reactor itself, I think, will come down largely after you have run the plant for a while and find out where it was that you were overly conservative when you designed it in the first place. I think you will discover, after you have run the PWR for a while and have perhaps put in 1 or 2 additional cores, that the water circulating system, the heat exchangers and the turbogenerators are, in fact, only perhaps a fraction as big as they should be to take the actual output of what you have out of the plant now that you know how to remove the bottlenecks. At that point somebody can come along and build a plant that, perhaps, wouldn't cost a great deal more than the PWR, but which will put out perhaps 2 or 3 times the output.

Admiral RICKOVER. It is too early now.

Mr. DAVIS. It is too early now and too early until you have run it and found out how to do these things. At that point you can build a plant which in capital cost—in terms of dollars per kilowatt—have become quite reasonable. At the same time you develop fuel cost where it is down to a point which is quite reasonable. At that point which, perhaps, is 3 or 4 years after you complete and operate your plant, you have a real sound basis for going ahead with a very much improved pressurized water reactor.

I think you have to take these things together and keep in mind that the things that bring down the cost in reactors are these two different

aspects. You have got to be able to do both of them. To do one of them alone is never going to make the grade.

Representative PRICE. How much is invested in the PWR right now?

Admiral RICKOVER. Investment in cost at the present time is $55 million for construction and about $40 million for research and development. This is exclusive of the cost of the steam plant, which is being borne by the Duquesne Light Co. I would say, roughly, the total expense of the PWR today is about $110 million.

Representative PRICE. Today.

Admiral RICKOVER. That is what we see will be the cost when it is finished about the end of the year. I am giving you overall cost.

Representative PRICE. By the time it is in operation?

Admiral RICKOVER. Yes sir. It looks today like roughly $110 million.

Representative PRICE. How much in excess of the original figure is that?

Admiral RICKOVER. I think Congress authorized originally $100 million for research and devolopment plus construction, which was $85 million for the reactor portion, so it is running over.

Mr. DAVIS. It was $85 million. You took out $15 million for the turbogenerator.

Admiral RICKOVER. About $100 million was the original estimate back in 1955. It has turned out to be about $110 million.

Representative PRICE. You have had these men working on this pressurized water reactor for about 5 years. I think they are probably among the best men in this field of reactors. Has any one of them ever expressed a desire to get into the business of building and testing gas-cooled reactors?

Admiral RICKOVER. Some of them have.

Representative HOLIFIELD. Do you need something in the way of a real challenge to keep these people now? Is there enough of a continuing challenge in improving the cores and other improvements on the PWR to keep your top people together or do they need something that would provide a real new challenge to them?

Admiral RICKOVER. I will put it this way. The people who are in this game, both in my organization in Washington and here, are not in it because of naval reactors alone. They are in this game in order to develop atomic energy in the United States. To them and to some extent this is true of me also, the naval program leads to this. So they would welcome a challenge of another type of reactor to work on. We have had discussions about this here at Bettis and in my organization and if the Commission decided to do this, we would be happy to take it on.

Certainly it would add more work for us, but we would make out. We would hire more people.

Representative HOLIFIELD. In other words, you could phase these people right into the program without damaging your large ship reactor.

Admiral RICKOVER. It always damages a little. We started out with one reactor, the mark 1, at Arco. Then as we undertook more reactor projects, we hired and trained more people. But all of the technology you learn on one type of reactor will add to another.

As I mentioned this morning, we are not starting off with novices. We are starting off with people who have, at least, a pretty good concept of what the design of a large scale reactor is. We would hope that we would have learned many lessons from what we have done in the past and not make all of the same mistakes.

Representative PRICE. Do any of them see any greater promise in a gas-cooled reactor than a pressurized water reactor?

Admiral RICKOVER. I think until you try out different types you can't say. I don't think you can hypothesize reactors. I think you have to try one of them out in order to find out.

Representative PRICE. Do they talk about the advantages of one over the other or what they think might be the advantage of one over the other?

Admiral RICKOVER. The major advantage of a gas-cooled reactor is that you can use natural uranium. If the policy of the country is to sell reactors abroad; if this is our national policy, you pretty much have to learn to design natural uranium reactors. Otherwise you force the countries to buy their fuel from this country if it is enriched uranium, or you force them to set up a uranium separation plant.

Representative HOLIFIELD. If you had the privilege of naming the type of reactor that you would like to go into, which one would you select?

Admiral RICKOVER. Gas cooled.

Representative HOLIFIELD. Gas rather than the homogeneous?

Admiral RICKOVER. Yes, sir.

Representative HOLIFIELD. Was the decision to go ahead with additional submarines in the pressurized-water field rather than in the sodium field based on the factor of sodium leakage?

Admiral RICKOVER. When we started out in the nuclear-submarine program we didn't know whether sodium was better than water, or vice versa. They both offered promise. As we went along—and before the *Sea Wolf* was finished—we recognized that water was better. By this time we had a water plant operating, so we then made the decision that for additional submarines we would go to water. We did that long before the *Sea Wolf* was operating, because we saw already that water was better than sodium for naval plants. However, we figured that we should go on and finish the job and try it out. We had to find out, and the only way you really find out is to operate the plant under service conditions.

The *Sea Wolf* is operating right now, and will keep on operating. If she develops another leak, we will have to take a look and see how expensive it is to repair. If it is too expensive, we may not continue operation. We are making plans now to replace the sodium reactor of the *Sea Wolf* with a pressurized-water type similar to the one that we have in the *Nautilus*.

Chairman DURHAM. Would there have to be any redesigning of the reactor to fit the *Sea Wolf?*

Admiral RICKOVER. We will use things we already have. There is plenty of room in the *Sea Wolf* to take a pressurized-water plant.

Representative PRICE. You are still running the *Sea Wolf* on shakedown?

Admiral RICKOVER. She is out operating right this minute. She will be at sea for about a month.

Mr. RAMEY. On the gas-cooled reactors, why can't we rely on the British for this information?

Admiral RICKOVER. It all depends on what philosophy you take on reactors. Normally, you can't learn the whole story from somebody else. You just cannot do it. You can get technical data, but if you really want to learn how to do something, you have got to do it yourself. Sure, you can get a lot of help from them, but you can't really learn unless you develop much of the technology in this country.

Chairman DURHAM. Why, then, are the British so anxious to get our information on these things?

Admiral RICKOVER. They are interested in water-cooled reactors, also. They want to get all the information they can so that, if it is necessary, they can try it out themselves. I did want to say a few more words about getting industry to do this job—which touched this off. I would like to talk for a couple of minutes on that.

Representative PRICE. Before you do that, could we get a list of the information on that project which has been disseminated to industry?

Admiral RICKOVER. Yes, sir; not only on the PWR, but the whole Navy program.

Representative PRICE. And also tell us how you get this out to industry?

Admiral RICKOVER. I will get something through the Commission on that to your committee.

(The information referred to follows:)

DECLASSIFICATION AND DISSEMINATION OF INFORMATION DEVELOPED IN THE NAVAL REACTORS AND PWR PROGRAMS

As of February 23, 1957, the following policy was established in the naval reactors and PWR programs:

(*a*) All information on the PWR plant at Shippingport is unclassified.

(*b*) All reactor technology developed on naval reactors is unclassified.

(*c*) All naval reactor design information is classified "confidential," "restricted data," or "defense information," as appropriate.

As a result of a document review conducted during March and April of this year at the Bettis plant, the Knolls Atomic Power Laboratory, and the Combustion Engineering Laboratory, over 5,000 classified naval reactor documents have been released for review and possible application to the AEC civilian application program. The information contained in these documents covers areas such as: reactor physics, reactor design, metallurgy, reactor plant components, and reactor control. To supplement this continuing document review, naval reactor laboratories will issue quarterly unclassified reports on the latest developments in reactor technology in these laboratories. These reports will be available to the public through the AEC's Technical Information Service at Oak Ridge, Tenn.

Representative HOLIFIELD. Is that released through the Commission?

Admiral RICKOVER. The Commission has set up a regular method of declassifying. What we are doing now is getting our laboratories to go over all of the information they have and put it in a form so it can be published.

Representative PRICE. Specifically, I meant the Shippingport project, but we would also like to have the information on other projects.

Admiral RICKOVER. I will give it to you for everything that we do.

Mr. FIELDS. May I say one thing at this point? On this question of adding another reactor project here, the Commission—I shouldn't speak for the Commission, but let me speak for myself at this point, which would be a recommendation, I suppose, to the Commission if we got to that point. I haven't seen anything the last year that I have

been around here to indicate that the people here are without work and don't have a lot to do and that there wouldn't be a serious problem if we were to confront this group with undertaking such a reactor as to just how much impact it would have on the naval program. I think there are two sides to this question, and I haven't seen any evidence that there isn't a lot to do here yet.

Chairman DURHAM. I would certainly have to be thoroughly convinced that it would in no way affect the Navy program before I would ever be for it. I think we face a serious challenge in submarines. After reviewing this program, there is no doubt in my mind that we are face to face with quite a vicious type of threat—not just a few weapons, but numbers and numbers of them.

Mr. FIELDS. Quite apart from the question of whether this country goes ahead with a gas-cooled reactor or not, there is the question of where it should go, and then another question is what you want to do.

Mr. DAVIS. I think it should be said that what we will get from the British on gas-cooled reactors is that we will find out what their economics are. We won't necessarily get the know-how with which to build one. I think it is important to recognize the difference between these two things, too.

Representative PRICE. What will we get, then, from the British?

Mr. DAVIS. We will certainly get enough information to evaluate the reactors with respect to what they can do. I don't think we will get enough so that we could, without doing quite a bit of development ourselves, actually build one similar to theirs or improve on it.

Representative PRICE. I thought there was some question about relying on British figures for the economics of their reactor.

Mr. DAVIS. I think what one has to do is to make his own figures, but base them on their costs. That is like trying to develop figures, for example, of what it would cost to build another PWR. You don't assume everything costs the same. You go through and make your own figures as to where it is going to be built and the conditions under which it is going to be built.

There is more to extrapolating the British reactor to United States figures than there is to extrapolating the PWR from here up to Rowe, Mass., for example. Nevertheless, I think it can be done and that there will be sufficient information to do this. However, if we gave somebody the job of manufacturing the fuel elements similar to the British fuel elements to put them into a gas-cooled reactor, there would be a lot of know-how which they would either have to go and get or they would have to learn by themselves. These, as I say, I think are related but still somewhat different considerations.

Chairman DURHAM. Do you have a proposal at the present time to build a gas-cooled reactor?

Mr. FIELDS. Aerojet.

Mr. DAVIS. We are going ahead with Aerojet. However, that is a very small, quite high temperature, closed-cycle, gas-turbine reactor.

Chairman DURHAM. Don't you have a regular power-producing reactor proposal before you of the gas-cooled type?

Mr. FIELDS. I believe Mr. Durham is referring to one under consideration by the Florida Power——

Mr. DAVIS. There is a Florida nuclear-power group.

Chairman DURHAM. At least you announced it several weeks ago.

Mr. DAVIS. We have had discussions with them. They have not

made a formal proposal to us yet. We have had a number of discussions. They are thinking about a heavy-water moderated reactor using natural uranium, either gas or heavy-water cooled. I think their proposal, when it finally comes in, will probably be, at least for the first year or so, to consider both gas cooled and heavy-water cooled and to make a selection later depending upon which looks the best. These would be quite different than the British reactors, which are graphite moderated. It would be more similar to what the Russians have said they are working on—gas-cooled, heavy-water moderated.

Representative HOLIFIELD. In computing the British costs, do you have any difficulty with respect to what allowances they are making for plutonium?

Mr. DAVIS. We have some ideas, but it depends so much on who has been doing the talking. I think in this case they haven't really decided yet.

Mr. FIELDS. We don't have any report that says, "This is the allowance we are making for it," if that is what you mean.

Mr. DAVIS. Actually with the Calder Hall reactor, you see, they are getting what they can for power, which is about 5 mills, which is what Central Electricity Authority will pay the Atomic Energy Authority for power. The plutonium will cost whatever it would have to cost to balance off the rest of the cost. With the Central Authority reactors, presumably they are going to do it the other way around. The Central Authority will sell the plutonium to the Atomic Energy Authority and they will try in their power cost to make up the difference. They are still trying to negotiate, as I understand it, to make things come out right but they haven't arrived at a final figure as far as I am able to find out. I don't know what the figure is.

Mr. FIELDS. I wonder if I could finish what I started to say.

Representative PRICE. Go ahead.

Mr. FIELDS. We started from the point that you have a rather complete research and development effort here in the field of water reactors. What concerns me, frankly, about the situation and the arguments that we have had between various groups on how to proceed with reactors is this: You look at this effort. It has been very expensive and it is going to be expensive for a good many years ahead if this is to be a strong effort here at this installation just in this area of water-cooled reactors. Similarly we have the effort at Argonne which is also in a water field, although this has been boiling-water reactors, and they are in breeding reactors and other aspects of the reactor field. We have a strong group at Oak Ridge in the homogeneous reactor field and in some other activities there. There are certain other groups like Los Alamos that are beginning to get into the plutonium type of reactor. These groups in themselves are going to be very expensive and have a yearly operating expense of anywhere from $20 million to $50 million per installation just to keep those going. They are going to be able to come up with fruitful developments for a long time to come. It is far more important, I think, to this country for those groups to stay strong and active and thoroughly engaged in their fields of endeavor which are in slightly different reactor-development areas, than it is to start building a certain number of new complete production plants or powerplants at any particular time.

Once in a while they will reach a certain stage where there should be some powerplants built. We are building powerplants—not necessarily big ones, but like the EBWR. However, I hope in the considerations ahead that we continue to support these main-line development efforts that are so important to the progress in the field. I think this concerns all of us who are sitting here as much as anything in the picture.

Admiral RICKOVER. I agree.

Mr. FIELDS. We admittedly should build some once in awhile.

Representative PRICE. If you don't build some once in awhile, you are not going to get any place. You are always going to have experimental projects.

Mr. FIELDS. It is a matter of judgment as to what kind you build. I agree there should be targets along the way. Maybe you set a target like the EBWR at Argonne at one stage and maybe next time it has to be as big as the Dresden reactor or something of that type.

Mr. DAVIS. Almost all reactor projects have reactor experiments.

Representative PRICE. You can't keep them in the experimental stage forever. You have got to advance.

Mr. DAVIS. What has happened here is that, for example, the boiling water reactor is being followed by the G. E. small boiling water reactor and about a year later will be followed by the full scale boiling-water reactor which is being built for Commonwealth. If this kind of development is picked up at the proper stage after reactor experiment, then I think you have got a very logical sequence of development of these reactor types. If you get one that is developed and looks like it is a really good idea and somebody ought to do it and nobody does it, eventually you have got a problem. I think this is the way, if it works, that it will probably work the best—at least to my mind.

Mr. RAMEY. However, Argonne is building your water technology—your boiling water—and they are doing the breeder type which are dissimilar types of reactors.

Mr. DAVIS. Very dissimilar.

Mr. RAMEY. North American has a sodium graphite program and is doing an organic moderated job, so you do have, shall we say, a precedent for other installations doing two different types of reactors. I think one question then is why couldn't Bettis do two different types of reactors? Why couldn't Bettis do the pressurized water and the gas-cooled? Granted that they would start out on a small one probably——

Mr. DAVIS. These other installations are not doing military projects at the same time.

Mr. RAMEY. Argonne started off on the naval reactor program as well as civilian reactors.

Mr. DAVIS. Oak Ridge is an installation where we have got one main civilian power reactor effort and one main military reactor effort; that is true.

Mr. FIELDS. It is possible certainly. It hasn't happened.

Representative PRICE. I think Admiral Rickover was about to make a statement. We yield the floor.

Admiral RICKOVER. I wanted to add a few words about what we are doing in getting industry into this picture. We are in the process of establishing heat-exchanger manufacturers, valve manufacturers,

pressure-vessel manufacturers—all on a competitive basis. Although they started with a naval project, these same organizations are capable of doing this work for civilian projects.

The last time I testified I mentioned that even for our naval program 86 percent of our money being spent for procurement, is being spent competitively and on competitive bids. This includes reactor cores, valves, instrumentation, and so forth. That is the thing I wanted to touch on for a couple of minutes. We now have Olin-Matheson, Combustion Engineering, Westinghouse Electric, Babcock & Wilcox, and Metals & Control Corp., at Attleboro, Mass., all engaged in building naval reactor cores. As these people get experience they will be available to make cores for anybody. We will soon have more than one company capable of bidding competitively for most of the items that go to make up a nuclear plant. We are also doing this with respect to zirconium on the same basis that the AEC handles zirconium procurement. The AEC is purchasing reactor cores for the Navy, but the Navy pays for them by transfer of funds.

Unless we do it this way we are going to be faced with the problem of duplicate facilities being set up by the Navy. Since cores are still in the developmental stage, I think that would be wrong. I think it ought to be under one Government agency so that we do not duplicate purchasing organizations, inspection groups, and so on. In this way it will be most economical for the Government.

I think it is very important that we not divert our efforts and have, for instance, the Air Force start getting people to make cores and the Navy start getting people to make cores. This early in the development stage, I think it is extremely important that one agency, the AEC, have charge of it.

Representative HOLIFIELD. I certainly agree with that.

Chairman DURHAM. I felt like that on reactors all the way through.

Admiral RICKOVER. There is one more think I must say which I have said many times before, but I would like to say it again. Had it not been for the Atomic Energy Commission and the Joint Congressional Committee we would not have any nuclear-powered naval vessel today. I think these two organizations and their way of operating deserve most of the credit.

Representative PRICE. Are there any further questions?

Chairman DURHAM. Do you have enough funds to carry out your work this year?

Admiral RICKOVER. No sir, no one ever does. You ought to know that, Mr. Durham, as many years as you have been in Congress. You ask a question like that. It is surprising.

I would like to answer your question though, Mr. Durham. The AEC has given me all the money that I have asked for in the naval program. The program is advancing rapidly, however. We can use more money.

Chairman DURHAM. Has the Navy given you any?

Admiral RICKOVER. The Navy hasn't given me as much as I have asked for. But Admiral Burke has stated that he would make more money available next year to carry out the program.

Representative PRICE. If there are no further questions, I want to close this meeting and to express our deep appreciation to Admiral Rickover and his organization, Mr. Geiger and his organization, and the Westinghouse people for this fine presentation. I don't see any

of the Westinghouse people here so I hope someone will convey our appreciation to them for this very kind reception to the committee. I think this has been most helpful and informative. I hope in the future our committee can get out to some of these installations and hold official meetings right on the scene while the problems are still fresh in our minds and cause us to raise questions, the answers to which will be helpful to the whole committee.

Chairman DURHAM. Mr. Chairman, I concur in your words. I was at Bettis with a former chairman in 1947, I believe—certainly in 1948—when we first broke ground. When you see such a plant as this today and the accomplishments which have developed since that time, you feel like your money has been spent for something worthwhile.

Mr. FIELDS. Mr. Chairman, may we say we appreciate your coming here and doing this. It is a boon to our morale and that of the people here to see such an interest. I am sure it will be useful to all of us. I hope you can do it other places too. It is most effective.

Representative PRICE. Our thanks to all of the people who testified here today. The committee will stand adjourned.

(Whereupon at 5:05 p. m. the meeting was adjourned.)

PARTICIPATION ACT FOR THE INTERNATIONAL ATOMIC ENERGY AGENCY

TUESDAY, JULY 2, 1957

CONGRESS OF THE UNITED STATES,
SUBCOMMITTEE ON AGREEMENTS FOR COOPERATION
OF THE JOINT COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The subcommittee met, pursuant to notice, at 10 a. m., in room P–38, the Capitol, Hon. John O. Pastore, chairman of the subcommittee, presiding.

Present: Senators Pastore (chairman of the subcommittee), Hickenlooper, and Bricker.

Representatives Durham (chairman of the Joint Committee), Price, Cole, and Jenkins.

Senator PASTORE. This is a meeting of the Subcommittee on Agreements for Cooperation of the Joint Committee on Atomic Energy. Notices of this meeting have been sent to all members of the committee, even though they are not members of the subcommittee, so that they could attend if they so desire.

This meeting is to consider the Participation Act for the International Atomic Energy Agency.

This bill was introduced in the House by Mr. Price, H. R. 8251, and by Mr. Cole, H. R. 8254. I introduced the bill in the Senate, S. 2341.

All three of these bills are identical and are the legislation which has been suggested by the Department of State and forwarded by the Secretary of State to the Speaker of the House and the President of the Senate.

While the treaty itself was passed by the Senate on June 18, the treaty has not yet been signed. The legislation we are considering today is to establish the rules within the United States for participating in the Agency. This act is similar to the Participation Act we have for the Unted Nations and many other international organizations.

The first section would give the title of the act as the "International Atomic Energy Agency Participation Act of 1957."

The second section permits the President to appoint a representative and a deputy representative to the Board of Governors, the General Conference, and to other organs of the Agency.

It also permits the President to appoint delegates to the General Conference. The President can also appoint representatives to other organs of the Agency.

The bill provides for the rates of pay for those designated to represent the United States at the Agency.

The Participation Act would require the participation of the United States to be in conformity with both the statute of the Agency and the Atomic Energy Act. The President is to report to the Congress on the Agency's activities at least once a year.

Section 4 requires the representatives of the United States to vote at the Agency in accordance with the instructions from the President.

Section 5 provides the authorization for the appropriations to carry into effect the actual participation of the United States through its representatives.

I now ask that S. 2341 be inserted in full in the record at this point.

(The bill, S. 2341, is as follows:)

[S. 2341, 85th Cong., 1st sess.]

A BILL To provide for the appointment of representatives of the United States in the organs of the International Atomic Energy Agency, and to make other provisions with respect to the participation of the United States in that Agency, and for other purposes

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That this Act may be cited as the "International Atomic Energy Participation Act of 1957."

SEC. 2. (a) The President, by and with the advice and consent of the Senate, shall appoint a representative and a deputy representative of the United States to the International Atomic Energy Agency (hereinafter referred to as the "Agency"), who shall hold office at the pleasure of the President. Such representative and deputy representative shall represent the United States on the Board of Governors of the Agency, may represent the United States at the General Conference, and may serve ex officio as United States representative on any organ of that Agency, and shall perform such other functions in connection with the participation of the United States in the Agency as the President may from time to time direct.

(b) The President, by and with the advice and consent of the Senate, may appoint or designate from time to time to attend a specified session or specified sessions of the General Conference of the Agency a representative of the United States and such number of alternates as he may determine consistent with the rules of procedure of the General Conference.

(c) The President may also appoint or designate from time to time such other persons as he may deem necessary to represent the United States in the organs of the Agency. The President may designate any officer of the United States Government, whose appointment is subject to confirmation by the Senate, to act, without additional compensation, for temporary periods as the representative of the United States on the Board of Governors of the Agency in the absence or disability of the representative and deputy representative appointed under section 2 (a) or in lieu of such representatives in connection with a specified subject matter.

(d) All persons appointed or designated in pursuance of authority contained in this section shall receive compensation at rates determined by the President upon the basis of duties to be performed but not in excess of rates authorized by sections 411 and 412 of the Foreign Service Act of 1946, as amended (22 U. S. C. 866, 867), for Chiefs of Mission and Foreign Service officers occupying positions of equivalent importance, except that no Member of the Senate or House of Representatives or officer of the United States who is designated under subsection (b) or subsection (c) of this section as a delegate or representative of the United States or as an alternate to attend any specified session or specified sessions of the General Conference shall be entitled to receive such compensation. Any person who receives compensation pursuant to the provisions of this subsection may be granted allowances and benefits not to exceed those received by Chiefs of Mission and Foreign Service officers occupying positions of equivalent importance.

SEC. 3. The participation of the United States in the International Atomic Energy Agency shall be consistent with and in furtherance of the purposes of the Agency set forth in its Statute and the policy concerning the development, use, and control of atomic energy set forth in the Atomic Energy Act of 1954, as amended. The President shall, from time to time as occasion may require, but not less than once each year, make reports to the Congress on the activities

of the International Atomic Energy Agency and on the participation of the United States therein.

SEC. 4. The representatives provided for in Section 2 hereof, when representing the United States in the organs of the International Atomic Energy Agency, shall, at all times, act in accordance with the instructions of the President, and such representatives shall, in accordance with such instructions, cast any and all votes under the Statute of the International Atomic Energy Agency.

SEC. 5. There is hereby authorized to be appropriated annually to the Department of State, out of any money in the Treasury not otherwise appropriated, such sums as may be necessary for the payment by the United States of its share of the expenses of the International Atomic Energy Agency as apportioned by the Agency in accordance with paragraph (D) of article XIV of the Statute of the Agency, and for all necessary salaries and expenses of the representatives provided for in section 2 hereof and of their appropriate staffs, including personal services without regard to the civil service laws and the Classification Act of 1949, as amended; travel expenses without regard to the Standardized Government Travel Regulations, as amended, the Travel Expense Act of 1949, as amended, and section 10 of the Act of March 3, 1933, as amended; salaries, expenses, and allowances of personnel and dependents as authorized by the Foreign Service Act of 1946, as amended; services as authorized by section 15 of the Act of August 2, 1946 (5 U. S. C. 55a); translating and other services, by contract; hire of passenger motor vehicles and other local transportation; printing and binding without regard to section II of the Act of March 1, 1919 (44 U. S. C. 111); official functions and courtesies; such sums as may be necessary to defray the expenses of United States participation in the Preparatory Commission for the International Atomic Energy Agency, established pursuant to annex I of the Statute of the International Atomic Energy Agency; and such other expenses as may be authorized by the Secretary of State.

Senator PASTORE. On June 19, because of the interest of the Senators in the problems discussed on the floor of the Senate during the ratification, I announced that public hearings would be held on the Participation Act to receive statements from interested Senators. I reextended that invitation on June 26 when I announced on the floor of the Senate that this hearing date had to be postponed until today, July 2. No Senators have requested permission thus far to appear or to file a statement. Therefore, I will turn to the witnesses from the executive branch.

Today we have representatives from the Department of State and the Atomic Energy Commission ready to appear before us.

I would like to suggest that first we hear from Mr. Francis Wilcox, Assistant Secretary of State for International Organization Affairs, who will deal with the technicalities of the Participation Act and with the general Department of State position.

Second, we will hear from Admiral Strauss of the Atomic Energy Commission, with respect to the Commission's views on this statute.

Third, I would like to round out this hearing with a statement from Ambassador Wadsworth as to the intent and scope of the statute in order to get the record complete for any questions which might be raised about the Agency in both Houses.

I believe that this is especially important, since this will be the first record of the Agency which will be presented to the House of Representatives for its consideration.

I have been told by the Department of State that the presentation by the three witnesses will take about a half hour. They have requested that there be a minimum of questioning until the complete presentation is over, at which time the three witnesses will be available for any questions the committee members might desire to ask.

Mr. Wilcox, will you please present your statement.

STATEMENT OF FRANCIS WILCOX, ASSISTANT SECRETARY OF STATE, ACCOMPANIED BY GERARD SMITH, SPECIAL ASSISTANT TO THE SECRETARY OF STATE FOR ATOMIC ENERGY

Mr. WILCOX. Mr. Chairman, your very succinct summary of the participation act has made my task much easier.

I appreciate this opportunity to appear before the committee to assist in presenting the views of the executive branch with respect to our participation in the International Atomic Energy Agency. As the committee knows, the President and the executive branch attach great importance to this Agency.

The passage of a participation act will give substance to our membership in the International Atomic Energy Agency. The President's original proposal for the establishment of such an agency, the subsequent 3½ years of negotiations, and United States membership in the Agency would be meaningless without the passage of this law to provide for United States representation in its organs and to authorize contributions to its expenses.

President Eisenhower's concept of an international organization designed to bring the most newly discovered force of nature, atomic energy, within the reach of every country, was greeted with great enthusiasm throughout the world. By its active participation, the United States will continue in its role of leadership in applying atomic energy to peaceful purposes.

The statute of the International Atomic Energy Agency sets out two major objectives for the Agency.

First:

> The agency shall seek to accelerate and enlarge the contribution of atomic energy to peace, health, and prosperity throughout the world.

And, second:

> It shall ensure, so far as it is able, that assistance provided by it or at its request under its supervision or control is not used in such a way as to further any military purpose.

More specifically, it is to assist international research on and practical applications of atomic energy; to make provision for materials, services, equipment, and facilities to meet the needs of such research and practical application; to foster the exchange of scientific and technical information and to encourage the exchange and training of scientists and experts in the atomic energy field; and to establish international standards of safety for the protection of health, and to minimize danger to life and property involved in peaceful uses of atomic energy.

In carrying out all these functions, the agency is to establish and administer safeguards designed to ensure that any assistance it renders to member countries is not used in such a way as to further any military purpose.

On June 18, the Senate, by a vote of 67 to 19, gave its advice and consent to United States ratification of the IAEA statute. This action was taken only after thorough examination of all aspects of the proposed Agency and the advantages of United States membership.

ADVANTAGES TO THE UNITED STATES

In his opening statement before the Senate Foreign Relations Committee in support of the ratification of the IAEA statute, Secretary Dulles emphasized these advantages:

First, the Agency will accelerate the peaceful development of the atom;

Second, the Agency will provide an effective system of safeguards to ensure the development of atomic energy with adequate security. The spread of nuclear technology and facilities throughout the world is inevitable.

If this expansion is unsupervised, the threat of nuclear weapons will increase proportionately. The International Atomic Energy Agency will be in a position to provide an international safeguard system, established and operated by all member states, which can guard against diversion to military purposes of materials and services made available to member countries under its auspices.

Third, the Agency will be the appropriate body to develop and promulgate international codes to protect the health and safety of the populations which are otherwise benefiting from atomic energy.

Fourth, by providing a channel for cooperation and coordination, the Agency can assure the most efficient use of the limited supply of skilled manpower in this highly technical field.

Fifth, the Agency may have a constructive impact on the solution of one of the most difficult problems in the disarmament field, the development of a satisfactory system for international inspection and control.

It can do this by providing concrete evidence that such a system can be agreed to and can be successful in operation. If progress of this kind were made, it would constitute a breakthrough of considerable significance.

Sixth, the openness which this system will promote may help to prevent the spread of nuclear weapons.

The availability of nuclear weapons to countries not now possessing them could seriously impede arms control. With the development of the peaceful atom taking place under international security provided by the Agency, nations will feel less impelled to develop nuclear weapons out of fear that their neighbors may be doing so.

Finally, the unusual degree of cooperation which has taken place thus far between West and East in this new and important field may show the way to cooperation and understanding in other areas of difference.

PROVISIONS OF PARTICIPATION ACT

It is within this framework that we now consider legislation to enable the United States to participate effectively as a member of the agency. This legislation follows the practice established in the United Nations and the other major international organizations in which we participate. In those cases, the administration requested and the Congress enacted similar legislation authorizing United States participation.

I would now like to comment briefly on the five substantive sections of the participation act that is before the committee.

94441—57——2

Section 2 (a) provides for the appointment by the President of a United States representative and deputy to the IAEA. The representative and his deputy are to represent the United States on the Board of Governors and may also serve on the United States delegation to the General Conference and also any other organ of the Agency.

Paragraph (b) provides that the President may in addition appoint a representative and alternates to attend specified sessions of the General Conference. This is much the same practice that is followed in making up the United States delegations to the United Nations and other international organizations.

As the chairman knows from his participation in the delegation for a specific session of the General Assembly, for example, representatives are appointed to serve in addition to Ambassador Lodge and his deputy, Ambassador Wadsworth.

Paragraph (c) provides for additional appointments as necessary.

Paragraph (d) of section 2 provides for the compensation of persons designated under this section.

In the initial period of the Agency's existence its program will of necessity be relatively small and the major activity will be in planning rather than implementation.

Consequently, in our judgment, the staff of the United States representative need not be large. Indeed, it ought to be quite small.

Our present thinking is that, in addition to the representative and his deputy, 1 political and 1 scientific adviser should provide adequate support for this initial period. There would also be an executive officer, and the necessary clerical assistance.

Section 3 provides that United States participation in the Agency as set forth in the statute shall be consistent with and in furtherance of the purposes of the Agency and the Atomic Energy Act of 1954. This section provides that the President is to report to Congress as occasion may require and at least once a year on the activities of the Agency and on United States participation therein. This we believe desirable in view of the deep interest of the Congress in the development of the peaceful uses of atomic energy.

The Department of State and the AEC will work closely together to prepare these reports in order to present to Congress information which is as complete and current as possible.

Of course, it is the intention and desire of the Department of State and the Atomic Energy Commission to go beyond this requirement and to keep Congress, and this committee, especially, informed on a more informal basis of major developments in the Agency. Appropriate officers of both agencies will be available on request to furnish information and answer questions.

Section 4 simply provides that the United States representatives will act and vote in accordance with instructions of the President. This language will permit the same close cooperation between the Department of State and the Atomic Energy Commission in backstopping the United States representative at the Agency that has characterized our negotiation of the statute and the subsequent work in the Preparatory Commission.

Section 5 authorizes the appropriation of funds annually to the Department of State for the payment of the United States share

in the expenses of the Agency, for the support of the permanent mission, for expenses in connection with conferences and meetings, and to defray the expenses of United States participation in the Preparatory Commission. Our present estimate indicates that these costs for the first year would be approximately as follows:

United States share, not to exceed one-third, of combined expenses of Preparatory Commission and IAEA in the first year, $2,300,000;

Support of permanent United States mission when at full strength during initial period, $200,000;

Expenses of United States delegations to conferences, $100,000.

Total, $2,600,000.

The first year's budget for the Agency has been estimated by the Preparatory Commission to be about $7 million, including 2 nonrecurring items, $500,000 to repay the United Nations loan on which the Preparatory Commission is now operating, and a $2 million working capital fund to cover contingencies.

In my opinion, the cost of the United States participation in the Agency is indeed modest when compared to the potential advantages to the United States.

I should say also it is quite modest when compared to the other international organizations in which the United States now participates.

Mr. Chairman, the International Atomic Energy Agency is about to become a reality. It is expected that in the near future the necessary number of ratifications to bring the Agency into existence will be deposited.

Since the conference to draft the Agency's statute concluded its deliberations last October, the Preparatory Commission, established by the conference, has been making rapid progress in arranging for the first meetings of the General Conference and the Board of Governors.

It has set October 1 of this year as the date for the meeting of the first General Conference, and the Board of Governors will meet soon thereafter. Both meetings will take place in Vienna, the city which is to be the headquarters of the Agency.

Mr. Chairman, this concludes my statement. Again, I want to thank the committee for giving me this opportunity to present the administration's views on this act.

Admiral Strauss and Ambassador Wadsworth, both of whom have devoted a great deal of attention to the establishment of this Agency, and both of whom know more about the statute certainly than I do, will doubtless wish to provide further information of interest to the committee. After that I shall of course, be glad to answer questions.

Mr. Gerard Smith of the State Department, who has had a great deal to do with the negotiating of statute, is also here, together with other officials from the State Department, Atomic Energy Agency, and I hope we will be able to answer satisfactorily any questions which the committee might have.

Senator PASTORE. Thank you, Mr. Wilcox.

Now we will hear from the Chairman of the Atomic Energy Commission, Mr. Strauss.

STATEMENT OF HON. LEWIS L. STRAUSS, CHAIRMAN, ACCOMPANIED BY A. A. WELLS, OFFICE OF GENERAL COUNSEL, ATOMIC ENERGY COMMISSION

Mr. STRAUSS. Mr. Chairman, my purpose in making this very short statement is simply to be on record as endorsing the participation.

I appreciate the opportunity to make a brief statement in support of the proposed International Atomic Energy Agency Participation Act.

My connection with the inception of the idea which has resulted in the atoms-for-peace program and with the Agency is, I believe, well known to you. I am convinced that the institution will be a substantial contribution to the peace of the world, and will be a necessity for world health and safety.

It is my understanding that legislation similar to the bill which is under consideration, is the customary means of providing for the appointment of United States representatives to international bodies and of making the necessary administrative arrangements to support United States participation in such organizations.

The provisions of the bill seem to me to provide an adequate basis for United States participation in the Agency and for furthering our national objectives designed to promote the peaceful uses of atomic energy as widely and as soon as practicable, with due regard to our own needs and to prudent consideration of security.

Section 3 of the bill provides that participation by the United States in the agency shall be consistent with the policy concerning the development, use, and control of atomic energy as set forth in the Atomic Energy Act of 1954, as amended.

This section recognizes the fundamental principles enunciated by the Congress to govern the activity of the United States agencies both at home and abroad in the peaceful uses of atomic energy.

It insures, therefore, that the disposition and use abroad of special nuclear material and atomic technology of the United States will be in keeping with the requirements of the Atomic Energy Act.

The Senate has now given its consent to United States ratification of the statute of the agency.

Prior to that action by the Senate, which I delivered before the Foreign Relations Committee and in which I outlined my understanding of what the agency was intended to accomplish, I also said that if the President had not proposed the agency initially in his speech to the United Nations on December 8, 1953, there would be a profound need now to invent such a body.

My reason for this statement is the pressing requirement for uniform, meaningful health and safety standards to govern the use, transportation, storage, and disposal of radioactive materials the world over.

This is one of the immediate functions of the agency. The prerequisite constitutional basis for United States participation in such an agency having now been accomplished, the passage of this participation act would make it possible to concentrate on the next task of establishing an effective organization and of initiating a sound program in which a system of prudent international safeguards will have first priority.

The agency's program, besides promoting the beneficial uses of the atom throughout the world, will provide the basis for necessary international agreements on security controls and on the standards of health and safety to which I have referred.

The particular importance of these is emphasized by the growing use of the peaceful atom in research, in industry, agriculture, and medicine and, of course, power.

Unregulated by a common standard, these activities can conceivably create widespread hazards and risks for populations well beyond the boundaries of the countries in which the materials are used.

I know of no way except through international cooperation to promote the use of the atom under standards of control and safety which will protect everyone, ourselves included, from these hazards.

It is for this reason that I am happy that we have reached this stage in atomic energy development and that you are today considering this participation act whose passage I must sincerely advocate.

Thank you, Mr. Chairman.

Senator PASTORE. Thank you, Mr. Strauss.

Now, Mr. Wadsworth.

STATEMENT OF HON. JAMES J. WADSWORTH, DEPUTY REPRESENTATIVE OF THE UNITED STATES TO THE UNITED NATIONS

Mr. WADSWORTH. Thank you very much, Mr. Chairman, also for the opportunity of appearing before you again.

I recall your most valuable services to the United States delegation to the conference on the statute last fall in New York.

I also recall with great pleasure your consistent and helpful interest in this matter from the very outset.

Mr. Chairman, it has been suggested that in my statement this morning I give my impressions of the negotiation of the statute, cite some of its salient features and discuss briefly the prospects for future development of the agency.

Since our primary purpose today is to concentrate on the participation act, my comments will be geared to foreshadowing the problems which the future United States representatives to the agency are likely to face once it is established.

To begin with, Mr. Chairman, I should like to reiterate my belief expressed in earlier hearings, that the negotiation of the statute was a remarkable and unusual experience. Here is a document signed by 80 nations after 3½ years of painstaking negotiations which nonetheless reflects all the basic elements of the United States proposal included in President Eisenhower's speech at the U. N. in December 1953.

The negotiation was certainly not one broad, smooth road to success and understanding free of detours or pitfalls.

But the power of an aroused public opinion, inspired by the President's noble concept of this agency, was so great that it was reflected time and again at the conference table in a determination to overcome all obstacles.

You will remember that for more than a year, in fact, almost 2 years, the Russians totally rejected our proposals, but when in late 1955 it became evident that others would join with the United States in pur-

suing the goal of atoms for peace, with or without the Soviets, they finally participated in the negotiation group.

At several points difficult and new problems arose, such as how are we to reconcile sovereign rights of nations with the needs for adequate safeguards against the diversion of atomic recourses to military uses, or how to distribute voting participation and responsibility in the key bodies of the agency.

These troublesome matters would never have been resolved were it not for the businesslike persistent determination which characterized the approach of all the key delegations during these negotiations.

If, as I hope, this spirit is maintained the establishment of this agency will become a symbol and a precedent for earnest worldwide cooperation in the quest for peace.

In turning to the statute, Mr. Chairman, it is not my intention to comment on all of its provisions. Unless members of the committee have questions on certain other articles, I shall confine my brief comments to articles III, V, IX, XI, XII, and XIV, which I think cast some light on the task which will face our representatives to the agency and thus afford us a basis for determining how to set up our arrangements for participating in the agency's activities.

Article III sets forth the functions of the Agency. These are broad in scope, but the activities in the early years are likely to be modest.

Thus, the United States representatives provided for in this participation act must sooner or later be equipped to form well-considered recommendations on a wide range of technical and political questions.

However, as Assistant Secretary Wilcox has said, the size and character of the staff they need and the nature of the backstopping and reporting arrangements can only be worked out as the Agency's plans and activities are further developed, and it is for this reason that present plans call for a very small group.

Article V deals with the role of the General Conference. The point of key significance for us today in considering the General Conference is that the United States was successful in placing in the Board of Governors the principal responsibility for policymaking for the Agency. This means that our representative on the board will have a key role in formulating policy recommendations and specific proposals relating to the Agency's program.

The General Conference, however, has important responsibilities. Among others, it reviews and approves the budget; it confirms the appointment of the director general of the Agency, and it elects 10 members of the Board of Governors.

Now, if the United States representative to the General Conference is to achieve our objectives in political negotiations of this character without substantial difficulty, we know from long experience that extensive and careful preparatory negotiations will be necessary on the part of our representative on the Board of Governors.

Article IX relates to the supply of materials. It should be noted that no nation is compelled to make materials available to the Agency. The decision to sell such materials and the terms on which they will be offered to the agency is up to the supplying government.

Working out recommendations on these terms, methods of delivery and similar problems will require the United States representatives to cope with many technical questions.

Before leaving this article, I would like to cite a key provision which is basic to the concept of the Agency. This provision is paragraph (j) of article IX, which reads as follows:

J. The materials made available pursuant to this article shall be used as determined by the Board of Governors in accordance with the provisions of this statute. No member shall have the right to require that the materials it makes available to the Agency be kept separately by the Agency, or to designate the specific project in which they must be used.

I mention this point, because it highlights the importance of the leadership which we expect to exert in the Board of Governors in examining and approving Agency projects which might call for materials being sent by the United States to some other country.

Article XI tells how the Agency's projects will be developed.

Application for Agency assistance to a project can be made by a member or groups of members. The Agency can assist members in obtaining financing, but cannot be required to undertake any guaranties or assume any financial responsibility itself.

The criteria which the Board must consider in deciding upon projects are set forth in paragraph (e). You can see from reading this paragraph that the Agency is going to give careful and exhaustive consideration to Agency projects before approving them and that the work of the United States representative on the Board of this Agency is going to be quite voluminous.

Article XII deals with safeguards against diversion of Agency assistance to military uses. This key article was carefully drawn to insure that the Agency would have the authority to do its safeguards job.

As Secretary Dulles has pointed out, and Assistant Secretary Wilcox just this morning, article XII may do more than make possible the acceleration of peaceful atomic development throughout the world. It may make, and I believe it will make, a positive contribution to solving the problem of nuclear disarmament.

In this article the Agency is given authority to send inspectors into the Territory of recipient governments, these inspectors—

who shall have access to all places and data and to any person who deals with materials, equipment, and facilities which are required by this statute to be safeguarded.

It can thus be seen that the United States Board member will be faced with many new technical and political problems as the Agency's safeguards policies evolve.

Article XIV is the financial one. It was drafted in a spirit of care and conservatism to avert the danger that the "have not" nations could ever launch the Agency on extravagant and unsound programs.

The Board's task of establishing appropriate charges for Agency materials, services, equipment, and facilities will require careful and resourceful thought.

Mr. Chairman, I have sought in these brief comments to point up the fact that the scope of the questions with which the Agency must deal will be broad. They will require that our representatives find solutions for novel political and technical problems of some complexity.

I do not believe that the United States delegation need be large in the early years. However, from my experience with the negotiations of the statute and I worked with the Preparatory Commission with

this Agency, I well know that the effective United States representation in this field requires active participation of staff drawn both from the Department and from the Atomic Energy Commission, and that the arrangements must be such that help will be at hand when the United States representative needs it.

The provision of this participation act will make possible the continuance of the cooperative arrangements which have well served the needs of the United States delegations to the negotiating group, to the conference on the statute, and to the Preparatory Commission.

I have no hesitation in supporting this proposed legislation which is to govern future participation in this great new venture.

Thank you, Mr. Chairman.

Senator PASTORE. Thank you, sir.

Mr. Smith is here from the State Department; do you desire to make a formal statement, too?

Mr. SMITH. No, thank you, Senator. I will be happy to try to answer any questions.

Senator PASTORE. Now, for the purpose of the record, I think at this point we ought to insert the statute.

If there is no objection, that will be done.

Secondly, I think we ought to insert here an analysis of the statute which was prepared by our staff, which is not too long; and

Thirdly, I think we ought to insert here in the record the letter addressed by Secretary of State John Foster Dulles to Senator Fulbright, with reference to an agreement of understanding.

(The material referred to follows:)

STATUTE OF THE INTERNATIONAL ATOMIC ENERGY AGENCY

Article I. Establishment of the Agency

The Parties hereto establish an International Atomic Energy Agency (hereinafter referred to as "the Agency") upon the terms and conditions hereinafter set forth.

Article II. Objectives

The Agency shall seek to accelerate and enlarge the contribution of atomic energy to peace, health, and prosperity throughout the world. It shall ensure, so far as it is able, that assistance provided by it or at its request or under its supervision or control is not used in such a way as to further any military purpose.

Article III. Functions

A. The Agency is authorized:

1. To encourage and assist research on, and development and practical application of, atomic energy for peaceful uses throughout the world; and, if requested to do so, to act as an intermediary for the purposes of securing the performance of services or the supplying of materials, equipment, or facilities by one member of the Agency for another; and to perform any operation or service useful in research on, or development or practical application of, atomic energy for peaceful purposes;

2. To make provision, in accordance with this Statute, for materials, services, equipment, and facilities to meet the needs of research on, and development and practical application of, atomic energy for peaceful purposes, including the production of electric power, with due consideration for the needs of the underdeveloped areas of the world;

3. To foster the exchange of scientific and technical information on peaceful use of atomic energy;

4. To encourage the exchange and training of scientists and experts in the field of peaceful uses of atomic energy;

5. To establish and administer safeguards designed to ensure that special fissionable and other materials, services, equipment, facilities, and information

made available by the Agency or at its request or under its supervision or control are not used in such a way as to further any military purpose; and to apply safeguards, at the request of the parties, to any bilateral or multilateral arrangement, or, at the request of a State, to any of that State's activities in the field of atomic energy;

6. To establish or adopt, in consultation and, where appropriate, in collaboration with the competent organs of the United Nations and with the specialized agencies concerned, standards of safety for protection of health and minimization of danger to life and property (including such standards for labour conditions), and to provide for the application of these standards to its own operations as well as to the operations making use of materials, services, equipment, facilities, and information made available by the Agency or at its request or under its control or supervision; and to provide for the application of these standards, at the request of the parties, to operations under any bilateral or multilateral arrangement, or, at the request of a State, to any of that State's activities in the field of atomic energy;

7. To acquire or establish any facilities, plant and equipment useful in carrying out its authorized functions, whenever the facilities, plant, and equipment otherwise available to it in the area concerned are inadequate or available only on terms it deems unsatisfactory.

B. In carrying out its functions, the Agency shall:

1. Conduct its activities in accordance with the purposes and principles of the United Nations to promote peace and international cooperation, and in conformity with policies of the United Nations furthering the establishment of safeguarded worldwide disarmament and in conformity with any international agreements entered into pursuant to such policies;

2. Establish control over the use of special fissionable materials received by the Agency, in order to ensure that these materials are used only for peaceful purposes;

3. Allocate its resources in such a manner as to secure efficient utilization and the greatest possible general benefit in all areas of the world, bearing in mind the special needs of the underdeveloped areas of the world;

4. Submit reports on its activities annually to the General Assembly of the United Nations and, when appropriate, to the Security Council: if in connection with the activities of the Agency there should arise questions that are within the competence of the Security Council, the Agency shall notify the Security Council, as the organ bearing the main responsibility for the maintenance of international peace and security, and may also take the measures open to it under this Statute, including those provided in paragraph C of article XII;

5. Submit reports to the Economic and Social Council and other organs of the United Nations on matters within the competence of these organs.

C. In carrying out its functions, the Agency shall not make assistance to members subject to any political, economic, military, or other conditions incompatible with the provisions of this Statute.

D. Subject to the provisions of this Statute and to the terms of agreement concluded between a State or a group of States and the Agency which shall be in accordance with the provisions of the Statute, the activities of the Agency shall be carried out with due observance of the sovereign rights of States.

Article IV, Membership

A. The initial members of the Agency shall be those States Members of the United Nations or of any of the specialized agencies which shall have signed this Statute within ninety days after it is opened for signature and shall have deposited an instrument of ratification.

B. Other members of the Agency shall be those States, whether or not Members of the United Nations or of any of the specialized agencies, which deposit an instrument of acceptance of this Statute after their membership has been approved by the General Conference upon the recommendation of the Board of Governors. In recommending and approving a State for membership, the Board of Governors and the General Conference shall determine that the State is able and willing to carry out the obligations of membership in the Agency, giving due consideration to its ability and willingness to act in accordance with the purposes and principles of the Charter of the United Nations.

C. The Agency is based on the principle of the sovereign equality of all its members, and all members, in order to ensure to all of them the rights and

94441—57——3

benefits resulting from membership, shall fulfill in good faith the obligations assumed by them in accordance with this Statute.

Article V. General Conference

A. A General Conference consisting of representatives of all members shall meet in regular annual session and in such special sessions as shall be convened by the Director General at the request of the Board of Governors or of a majority of members. The sessions shall take place at the headquarters of the Agency unless otherwise determined by the General Conference.

B. At such sessions, each member shall be represented by one delegate who may be accompanied by alternates and by advisers. The cost of attendance of any delegation shall be borne by the member concerned.

C. The General Conference shall elect a President and such other officers as may be required at the beginning of each session. They shall hold office for the duration of the session. The General Conference, subject to the provisions of this Statute, shall adopt its own rules of procedure. Each member shall have one vote. Decisions pursuant to paragraph H of article XIV, paragraph C of article XVIII, and paragraph B of article XIX shall be made by a two-thirds majority of the members present and voting. Decisions on other questions, including the determination of additional questions or categories of questions to be decided by a two-thirds majority, shall be made by a majority of the members present and voting. A majority of members shall constitute a quorum.

D. The General Conference may discuss any questions or any matters within the scope of this Statute or relating to the powers and functions of any organs provided for in this Statute, and may make recommendations to the membership of the Agency or to the Board of Governors or to both on any such questions or matters.

E. The General Conference shall:

1. Elect members of the Board of Governors in accordance with article VI;
2. Approve States for membership in accordance with article IV;
3. Suspend a member from the privileges and rights of membership in accordance with article XIX;
4. Consider the annual report of the Board;
5. In accordance with article XIV, approve the budget of the Agency recommended by the Board or return it with recommendations as to its entirety or parts to the Board, for resubmission to the General Conference;
6. Approve reports to be submitted to the United Nations as required by the relationship agreement between the Agency and the United Nations, except reports referred to in paragraph C of article XII, or return them to the Board with its recommendations;
7. Approve any agreement or agreements between the Agency and the United Nations and other organizations as provided in article XVI or return such agreements with its recommendations to the Board, for resubmission to the General Conference;
8. Approve rules and limitations regarding the exercise of borrowing powers by the Board, in accordance with paragraph G of article XIV; approve rules regarding the acceptance of voluntary contributions to the Agency; and approve, in accordance with paragraph F of article XIV, the manner in which the general fund referred to in that paragraph may be used;
9. Approve amendments to this Statute in accordance with paragraph C of article XVIII;
10. Approve the appointment of the Director General in accordance with paragraph A of article VII.

F. The General Conference shall have the authority:

1. To take decisions on any matter specifically referred to the General Conference for this purpose by the Board;
2. To propose matters for consideration by the Board and request from the Board reports on any matter relating to the functions of the Agency.

Article VI. Board of Governors

A. The Board of Governors shall be composed as follows:

1. The outgoing Board of Governors (or in the case of the first Board, the Preparatory Commission referred to in Annex I) shall designate for membership on the Board the five members most advanced in the technology of atomic energy including the production of source materials and the member most advanced in

the technology of atomic energy including the production of source materials in each of the following areas not represented by the aforesaid five:

(1) North America
(2) Latin America
(3) Western Europe
(4) Eastern Europe
(5) Africa and the Middle East
(6) South Asia
(7) South East Asia and the Pacific
(8) Far East

2. The outgoing Board of Governors (or in the case of the first Board, the Preparatory Commission referred to in Annex I) shall designate for membership on the Board two members from among the following other producers of source materials: Belgium, Czechoslovakia, Poland, and Portugal; and shall also designate for membership on the Board one other member as a supplier of technical assistance. No member in this category in any one year will be eligible for redesignation in the same category for the following year.

3. The General Conference shall elect ten members to membership on the Board of Governors, with due regard to equitable representation on the Board as a whole of the members in the areas listed in subparagraph A-1 of this article, so that the Board shall at all times include in this category a representative of each of those areas except North America. Except for the five members chosen for a term of one year in accordance with paragraph D of this article, no member in this category in any one term of office will be eligible for reelection in the same category for the following term of office.

B. The designations provided for in subparagraphs A-1 and A-2 of this article shall take place not less than sixty days before each regular annual session of the General Conference. The elections provided for in subparagraph A-3 of this article shall take place at regular annual sessions of the General Conference.

C. Members represented on the Board of Governors in accordance with subparagraph A-1 and A-2 of this article shall hold office from the end of the next regular annual session of the General Conference after their designation until the end of the following regular annual session of the General Conference.

D. Members represented on the Board of Governors in accordance with subparagraph A-3 of this article shall hold office from the end of the regular annual session of the General Conference at which they are elected until the end of the second regular annual session of the General Conference thereafter. In the election of these members for the first Board, however, five shall be chosen for a term of one year.

E. Each member of the Board of Governors shall have one vote. Decisions on the amount of the Agency's budget shall be made by a two-thirds majority of those present and voting, as provided in paragraph H of article XIV. Decisions on other questions, including the determination of additional questions or categories of questions to be decided by a two-thirds majority, shall be made by a majority of those present and voting. Two-thirds of all members of the Board shall constitute a quorum.

F. The Board of Governors shall have authority to carry out the functions of the Agency in accordance with this Statute, subject to its responsibilities to the General Conference as provided in this Statute.

G. The Board of Governors shall meet at such times as it may determine. The meetings shall take place at the headquarters of the Agency unless otherwise determined by the Board.

H. The Board of Governors shall elect a Chairman and other officers from among its members and, subject to the provisions of this Statute, shall adopt its own rules of procedure.

I. The Board of Governors may establish such committees as it deems advisable. The Board may appoint persons to represent it in its relations with other organizations.

J. The Board of Governors shall prepare an annual report to the General Conference concerning the affairs of the Agency and any projects approved by the Agency. The Board shall also prepare for submission to the General Conference such reports as the Agency is or may be required to make to the United Nations or to any other organization the work of which is related to that of the Agency. These reports, along with the annual reports, shall be submitted to members of the Agency at least one month before the regular annual session of the General Conference.

Article VII. Staff

A. The staff of the Agency shall be headed by a Director General. The Director General shall be appointed by the Board of Governors with the approval of the General Conference for a term of four years. He shall be the chief administrative officer of the Agency.

B. The Director General shall be responsible for the appointment, organization, and functioning of the staff and shall be under the authority of and subject to the control of the Board of Governors. He shall perform his duties in accordance with regulations adopted by the Board.

C. The staff shall include such qualified scientific and technical and other personnel as may be required to fulfil the objectives and functions of the Agency. The Agency shall be guided by the principle that its permanent staff shall be kept to a minimum.

D. The paramount consideration in the recruitment and employment of the staff and in the determination of the conditions of service shall be to secure employees of the highest standards of efficiency, technical competence, and integrity. Subject to this consideration, due regard shall be paid to the contributions of members of the Agency and to the importance of recruiting the staff on as wide a geographical basis as possible.

E. The terms and conditions on which the staff shall be appointed, remunerated, and dismissed shall be in accordance with regulations made by the Board of Governors, subject to the provisions of this Statute and to general rules approved by the General Conference on the recommendation of the Board.

F. In the performance of their duties, the Director General and the staff shall not seek or receive instructions from any source external to the Agency. They shall refrain from any action which might reflect on their position as officials of the Agency; subject to their responsibilities to the Agency, they shall not disclose any industrial secret or other confidential information coming to their knowledge by reason of their official duties for the Agency. Each member undertakes to respect the international character of the responsibilities of the Director General and the staff and shall not seek to influence them in the discharge of their duties.

G. In this article the term "staff" includes guards.

Article VIII. Exchange of information

A. Each members should make available such information as would, in the judgement of the member, be helpful to the Agency.

B. Each member shall make available to the Agency all scientific information developed as a result of assistance extended by the Agency pursuant to article XI.

C. The Agency shall assemble and make available in an accessible form the information made available to it under paragraphs A and B of this article. It shall take positive steps to encourage the exchange among its members of information relating to the nature and peaceful uses of atomic energy and shall serve as an intermediary among its members for this purpose.

Article IX. Supplying of materials

A. Members may make available to the Agency such quantities of special fissionable materials as they deem advisable and on such terms as shall be agreed with the Agency. The materials made available to the Agency may, at the discretion of the member making them available, be stored either by the member concerned or, with the agreement of the Agency, in the Agency's depots.

B. Members may also make available to the Agency source materials as defined in article XX and other materials. The Board of Governors shall determine the quantities of such materials which the Agency will accept under agreements provided for in article XIII.

C. Each member shall notify the Agency of the quantities, form, and composition of special fissionable materials, source materials, and other materials which that member is prepared, in conformity with its laws, to make available immediately or during a period specified by the Board of Governors.

D. On request of the Agency a member shall, from the materials which it has made available, without delay deliver to another member or group of members such quantities of such materials as the Agency may specify, and shall without delay deliver to the Agency itself such quantities of such materials as are really necessary for operations and scientific research in the facilities of the Agency.

E. The quantities, form and composition of materials made available by any member may be changed at any time by the member with the approval of the Board of Governors.

F. An initial notification in accordance with paragraph C of this article shall be made within three months of the entry into force of this Statute with respect to the member concerned. In the absence of a contrary decision of the Board of Governors, the materials initially made available shall be for the period of the calendar year succeeding the year when this Statute takes effect with respect to the member concerned. Subsequent notifications shall likewise, in the absence of a contrary action by the Board, relate to the period of the calendar year following the notification and shall be made no later than the first day of November of each year.

G. The Agency shall specify the place and method of delivery and, where appropriate, the form and composition, of materials which it has requested a member to deliver from the amounts which that member has notified the Agency it is prepared to make available. The Agency shall also verify the quantities of materials delivered and shall report those quantities periodically to the members.

H. The Agency shall be responsible for storing and protecting materials in its possession. The Agency shall ensure that these materials shall be safeguarded against (1) hazards of the weather, (2) unauthorized removal or diversion, (3) damage or destruction, including sabotage, and (4) forcible seizure. In storing special fissionable materials in its possession, the Agency shall ensure the geographical distribution of these materials in such a way as not to allow concentration of large amounts of such materials in any one country or region of the world.

I. The Agency shall as soon as practicable establish or acquire such of the following as may be necessary:

1. Plant, equipment, and facilities for the receipt, storage, and issue of materials;
2. Physical safeguards;
3. Adequate health and safety measures;
4. Control laboratories for the analysis and verification of materials received;
5. Housing and administrative facilities for any staff required for the foregoing.

J. The materials made available pursuant to this article shall be used as determined by the Board of Governors in accordance with the provisions of this Statute. No member shall have the right to require that the materials it makes available to the Agency be kept separately by the Agency or to designate the specific project in which they must be used.

Article X. Services, equipment, and facilities

Members may make available to the Agency services, equipment, and facilities which may be of assistance in fulfilling the Agency's objectives and functions.

Article XI. Agency projects

A. Any member or group of members of the Agency desiring to set up any project for research on, or development or practical application of atomic energy for peaceful purposes may request the assistance of the Agency in securing special fissionable and other materials, services, equipment, and facilities necessary for this purpose. Any such request shall be accompanied by an explanation of the purpose and extent of the project and shall be considered by the Board of Governors.

B. Upon request, the Agency may also assist any member or group of members to make arrangements to secure necessary financing from outside sources to carry out such projects. In extending this assistance, the Agency will not be required to provide any guarantees or to assume any financial responsibility for the project.

C. The Agency may arrange for the supplying of any materials, services, equipment, and facilities necessary for the project by one or more members or may itself undertake to provide any or all of these directly, taking into consideration the wishes of the member or members making the request.

D. For the purpose of considering the request, the Agency may send into the territory of the member or group of members making the request a person or persons qualified to examine the project. For this purpose the Agency may,

with the approval of the member or group of members making the request, use members of its own staff or employ suitably qualified nationals of any member.

E. Before approving a project under this article, the Board of Governors shall give due consideration to:

1. The usefulness of the project, including its scientific and technical feasibility;

2. The adequacy of plans, funds, and technical personnel to assure the effective execution of the project;

3. The adequacy of proposed health and safety standards for handling and storing materials and for operating facilities;

4. The inability of the member or group of members making the request to secure the necessary finances, materials, facilities, equipment, and services;

5. The equitable distribution of materials and other resources available to the Agency;

6. The special needs of the underdeveloped areas of the world; and

7. Such other matters as may be relevant.

F. Upon approving a project, the Agency shall enter into an agreement with the member or group of members submitting the project, which agreement shall:

1. Provide for allocation to the project of any required special fissionable or other materials;

2. Provide for transfer of special fissionable materials from their then place of custody, whether the materials be in the custody of the Agency or of the member making them available for use in Agency projects, to the member or group of members submitting the project, under conditions which ensure the safety of any shipment required and meet applicable health and safety standards;

3. Set forth the terms and conditions, including charges, on which any materials, services, equipment, and facilities are to be provided by the Agency itself, and, if any such materials, services, equipment, and facilities are to be provided by a member, the terms and conditions as arranged for by the member or group of members submitting the project and the supplying member;

4. Include undertakings by the member or group of members submitting the project: (*a*) that the assistance provided shall not be used in such a way as to further any military purpose; and (*b*) that the project shall be subject to the safeguards provided for in article XII, the relevant safeguards being specified in the agreement;

5. Make appropriate provision regarding the rights and interests of the Agency and the member or members concerned in any inventions or discoveries, or any patents therein, arising from the project;

6. Make appropriate provision regarding settlement of disputes;

7. Include such other provisions as may be appropriate.

G. The provisions of this article shall also apply where appropriate to a request for materials, services, facilities, or equipment in connexion with an existing project.

Article XII. Agency Safeguards

A. With respect to any Agency project, or other arrangement where the Agency is requested by the parties concerned to apply safeguards, the Agency shall have the following rights and responsibilities to the extent relevant to the project or arrangement:

1. To examine the design of specialized equipment and facilities, including nuclear reactors, and to approve it only from the viewpoint of assuring that it will not further any military purpose, that it complies with applicable health and safety standards, and that it will permit effective application of the safeguards provided for in this article;

2. To require the observance of any health and safety measures prescribed by the Agency;

3. To require the maintenance and production of operating records to assist in ensuring accountability for source and special fissionable materials used or produced in the project or arrangement;

4. To call for and receive progress reports;

5. To approve the means to be used for the chemical processing of irradiated materials solely to ensure that this chemical processing will not lend itself to diversion of materials for military purposes and will comply with applicable health and safety standards; to require that special fissionable materials recovered or produced as a by-product be used for peaceful purposes under continuing Agency safeguards for research or in reactors, existing or under construction, specified by the member or members concerned; and to require deposit with the

Agency of any excess of any special fissionable materials recovered or produced as a by-product over what is needed for the above-stated uses in order to prevent stockpiling of these materials, provided that thereafter at the request of the member or members concerned special fissionable materials so deposited with the Agency shall be returned promptly to the member or members concerned for use under the same provisions as stated above;

6. To send into the territory of the recipient State or States inspectors, designated by the Agency after consultation with the State or States concerned, who shall have access at all times to all places and data and to any person who by reason of his occupation deals with materials, equipment, or facilities which are required by this Statute to be safeguarded, as necessary to account for source and special fissionable materials supplied and fissionable products and to determine whether there is compliance with the undertaking against use in furtherance of any military purpose referred to in subparagraph F-4 of article XI, with the health and safety measures referred to in subparagraph A-2 of this article, and with any other conditions prescribed in the agreement between the Agency and the State or States concerned. Inspectors designated by the Agency shall be accompanied by representatives of the authorities of the State concerned, if that State so requests, provided that the inspectors shall not thereby be delayed or otherwise impeded in the exercise of their functions;

7. In the event of noncompliance and failure by the recipient State or States to take requested corrective steps within a reasonable time, to suspend or terminate assistance and withdraw any materials and equipment made available by the Agency or a member in furtherance of the project.

B. The Agency shall, as necessary, establish a staff of inspectors. The staff of inspectors shall have the responsibility of examining all operations conducted by the Agency itself to determine whether the Agency is complying with the health and safety measures prescribed by it for application to projects subject to its approval, supervision or control, and whether the Agency is taking adequate measures to prevent the source and special fissionable materials in its custody or used or produced in its own operations from being used in furtherance of any military purpose. The Agency shall take remedial action forthwith to correct any noncompliance or failure to take adequate measures.

C. The staff of inspectors shall also have the responsibility of obtaining and verifying the accounting referred to in sub-paragraph A-6 of this article and of determining whether there is compliance with the undertaking referred to in subparagraph A-2 of this article, and with all other conditions of the project prescribed in the agreement between the Agency and the State or States concerned. The inspectors shall report any noncompliance to the Director General who shall thereupon transmit the report to the Board of Governors. The Board shall call upon the recipient State or States to remedy forthwith any noncompliance which it finds to have occurred. The Board shall report the noncompliance to all members and to the Security Council and General Assembly of the United Nations. In the event of failure of the recipient State or States to take fully corrective action within a reasonable time, the Board may take one or both of the following measures: direct curtailment or suspension of assistance being provided by the Agency or by a member, and call for the return of materials and equipment made available to the recipient member or group of members. The Agency may also, in accordance with article XIX, suspend any noncomplying member form the exercise of the privileges and rights of membership.

Article XIII. Reimbursement of Members

Unless otherwise agreed upon between the Board of Governors and the members furnishing to the Agency materials, services, equipment, or facilities, the Board shall enter into an agreement with such member providing for reimbursement for the items furnished.

Article XIV. Finance

A. The Board of Governors shall submit to the General Conference the annual budget estimates for the expenses of the Agency. To facilitate the work of the Board in this regard, the Director General shall initially prepare the budget estimates. If the General Conference does not approve the estimates, it shall return them together with its recommendations to the Board. The Board shall then submit further estimates to the General Conference for its approval.

B. Expenditures of the Agency shall be classified under the following categories:

1. Administrative expenses: these shall include:

(a) Costs of the staff of the Agency other than the staff employed in connexion with materials, services, equipment, and facilities referred to in subparagraph B-2 below; costs of meetings; and expenditures required for the preparation of Agency projects and for the distribution of information;

(b) Costs of implementing the safeguards referred to in article XII in relation to Agency projects or, under subparagraph A-5 of article III, in relation to any bilateral or multilateral arrangement, together with the costs of handling and storage of special fissionable material by the Agency other than the storage and handling charges referred to in paragraph E below;

2. Expenses, other than those included in sub-paragraph 1 of this paragraph in connection with any materials, facilities, plant, and equipment acquired or established by the Agency in carrying out its authorized functions, and the costs of materials, services, equipment, and facilities provided by it under agreements with one or more members.

C. In fixing the expenditures under subparagraph B-1 (b) above, the Board of Governors shall deduct such amounts as are recoverable under agreements regarding the application of safeguards between the Agency and parties to bilateral or multilateral arrangements.

D. The Board of Governors shall apportion the expenses referred to in subparagraph B-1 above, among members in accordance with a scale to be fixed by the General Conference. In fixing the scale the General Conference shall be guided by the principles adopted by the United Nations in assessing contributions of Member States to the regular budget of the United Nations.

E. The Board of Governors shall establish periodically a scale of charges, including reasonable uniform storage and handling charges, for materials, services, equipment, and facilities furnished to members by the Agency. The scale shall be designed to produce revenues for the Agency adequate to meet the expenses and costs referred to in subparagraph B-2 above, less any voluntary contributions which the Board of Governors may, in accordance with paragraph F, apply for this purpose. The proceeds of such charges shall be placed in a separate fund which shall be used to pay members for any materials, services, equipment, or facilities furnished by them and to meet other expenses referred to in subparagraph B-2 above which may be incurred by the Agency itself.

F. Any excess of revenues referred to in paragraph E over the expenses and costs there referred to, and any voluntary contributions to the Agency, shall be placed in a general fund which may be used as the Board of Governors, with the approval of the General Conference, may determine.

G. Subject to rules and limitations approved by the General Conference, the Board of Governors shall have the authority to exercise borrowing powers on behalf of the Agency without, however, imposing on members of the Agency any liability in respect of loans entered into pursuant to this authority, and to accept voluntary contributions made to the Agency.

H. Decisions of the General Conference on financial questions and of the Board of Governors on the amount of the Agency's budget shall require a two-thirds majority of those present and voting.

Article XV. Privileges and Immunities

A. The Agency shall enjoy in the territory of each member such legal capacity and such privileges and immunities as are necessary for the exercise of its functions.

B. Delegates of members together with their alternates and advisers, Governors appointed to the Board together with their alternates and advisers, and the Director General and the staff of the Agency, shall enjoy such privileges and immunities as are necessary in the independent exercise of their functions in connection with the Agency.

C. The legal capacity, privileges, and immunities referred to in this article shall be defined in a separate agreement or agreements between the Agency, represented for this purpose by the Director General acting under instructions of the Board of Governors, and the members.

Article XVI. Relationship With Other Organizations

A. The Board of Governors, with the approval of the General Conference, is authorized to enter into an agreement or agreements establishing an ap-

propriate relationship between the Agency and the United Nations and any other organizations the work of which is related to that of the Agency.

B. The agreement or agreements establishing the relationship of the Agency and the United Nations shall provide for:

1. Submission by the Agency of reports as provided for in subparagraphs B-4 and B-5 of article III;

2. Consideration by the Agency of resolutions relating to it adopted by the General Assembly or any of the Councils of the United Nations and the submission of reports, when requested, to the appropriate organ of the United Nations on the action taken by the Agency or by its members in accordance with this Statute as a result of such consideration.

Article XVII. Settlement of Disputes

A. Any question or dispute concerning the interpretation or application of this Statute which is not settled by negotiation shall be referred to the International Court of Justice in conformity with the Statute of the Court unless the parties concerned agree on another mode of settlement.

B. The General Conference and the Board of Governors are separately empowered, subject to authorization from the General Assembly of the United Nations, to request the International Court of Justice to give an advisory opinion on any legal question arising within the scope of the Agency's activities.

Article XVIII. Amendments and Withdrawals

A. Amendments to this Statute may be proposed by any member. Certified copies of the text of any amendment proposed shall be prepared by the Director General and communicated by him to all members at least ninety days in advance of its consideration by the General Conference.

B. At the fifth annual session of the General Conference following the coming into force of this Statute, the question of a general review of the provisions of this Statute shall be placed on the agenda of that session. On approval by a majority of the members present and voting, the review will take place at the following General Conference. Thereafter, proposals on the question of a general review of this Statute may be submitted for decision by the General Conference under the same procedure.

C. Amendments shall come into force for all members when:

(i) Approved by the General Conference by a two-thirds majority of those present and voting after consideration of observations submitted by the Board of Governors on each proposed amendment, and

(ii) Accepted by two-thirds of all the members in accordance with their respective constitutional processes. Acceptance by a member shall be effected by the deposit of an instrument of acceptance with the depositary Government referred to in paragraph C of article XXI.

D. At any time after five years from the date when this Statute shall take effect in accordance with paragraph E of article XXI or whenever a member is unwilling to accept an amendment to this Statute, it may withdraw from the Agency by notice in writing to that effect given to the depositary Government referred to in paragraph C of article XXI, which shall promptly inform the Board of Governors and all members.

E. Withdrawal by a member from the Agency shall not affect its contractual obligations entered into pursuant to article XI or its budgetary obligations for the year in which it withdraws.

Article XIX. Suspension of Privileges

A. A members of the Agency which is in arrears in the payment of its financial contributions to the Agency shall have no vote in the Agency if the amount of its arrears equals or exceeds the amount of the contributions due from it for the preceding two years. The General Conference may, nevertheless, permit such a member to vote if it is satisfied that the failure to pay is due to conditions beyond the control of the member.

B. A member which has persistently violated the provisions of this Statute or of any agreement entered into by it pursuant to this Statute may be suspended from the exercise of the privileges and rights of membership by the General Conference acting by a two-thirds majority of the members present and voting upon recommendation by the Board of Governors.

94441—57——4

Article XX. Definitions

As used in this Statute:

1. The term "special fissionable material" means plutonium–239; uranium–233; uranium enriched in the isotopes 235 or 233; any material containing one or more of the foregoing; and such other fissionable material as the Board of Governors shall from time to time determine; but the term "special fissionable material" does not include source material.

2. The term "uranium enriched in the isotopes 235 or 233" means uranium containing the isotopes 235 or 233 or both in an amount such that the abundance ratio of the sum of these isotopes to the isotope 238 is greater than the ratio of the isotope 235 to the isotope 238 occurring in nature.

3. The term "source material" means uranium containing the mixture of isotopes occurring in nature; uranium depleted in the isotope 235; thorium; any of the foregoing in the form of metal, alloy, chemical compound, or concentrate; any other material containing one or more of the foregoing in such concentration as the Board of Governors shall from time to time determine; and such other material as the Board of Governors shall from time to time determine.

Article XXI. Signature, Acceptance, and Entry Into Force

A. This Statute shall be open for signature on 26 October 1956 by all States Members of the United Nations or of any of the specialized agencies and shall remain open for signature by those States for a period of ninety days.

B. The signatory States shall become parties to this Statute by deposit of an instrument of ratification.

C. Instruments of ratification by signatory States and instruments of acceptance by States whose membership has been approved under paragraph B of article IV of this Statute shall be deposited with the Government of the United States of America, hereby designated as depositary Government.

D. Ratification or acceptance of this Statute shall be effected by States in accordance with their respective constitutional processes.

E. This Statute, apart from the Annex, shall come into force when eighteen States have deposited instruments of ratification in accordance with paragraph B of this article, provided that such eighteen States shall include at least three of the following States: Canada, France, the Union of Soviet Socialist Republics, the United Kingdom of Great Britain and Northern Ireland, and the United States of America. Instruments of ratification and instruments of acceptance deposited thereafter shall take effect on the date of their receipt.

F. The depositary Government shall promptly inform all States signatory to this Statute of the date of each deposit of ratification and the date of entry into force of the Statute. The depositary Government shall promptly inform all signatories and members of the dates on which States subsequently become parties thereto.

G. The Annex to this Statute shall come into force on the first day this Statute is open for signature.

Article XXII. Registration With the United Nations

A. This Statute shall be registered by the depositary Government pursuant to Article 102 of the Charter of the United Nations.

B. Agreements between the Agency and any member or members, agreements between the Agency and any other organization or organizations, and agreements between members subject to approval of the Agency, shall be registered with the Agency. Such agreements shall be registered by the Agency with the United Nations if registration is required under Article 102 of the Charter of the United Nations.

Article XXIII. Authentic Texts and Certified Copies

This Statute, done in the Chinese, English, French, Russian and Spanish languages, each being equally authentic, shall be deposited in the archives of the depositary Government. Duly certified copies of this Statute shall be transmitted by the depositary Government to the Governments of the other signatory States and to the Governments of States admitted to membership under paragraph B of article IV.

In witness whereof the undersigned, duly authorized, have signed this Statute.

Done at the Headquarters of the United Nations, this twenty-sixth day of October, one thousand nine hundred and fifty-six.

ANNEX I. PREPARATORY COMMISSION

A. A Preparatory Commission shall come into existence on the first day this Statute is open for signature. It shall be composed of one representative each of Australia, Belgium, Brazil, Canada, Czechoslovakia, France, India, Portugal, Union of South Africa, Union of Soviet Socialist Republics, United Kingdom of Great Britain and Northern Ireland, and United States of America, and one representative each of six other States to be chosen by the International Conference on the Statute of the International Atomic Energy Agency. The Preparatory Commission shall remain in existence until this Statute comes into force and thereafter until the General Conference has convened and a Board of Governors has been selected in accordance with article VI.

B. The expenses of the Preparatory Commission may be met by a loan provided by the United Nations and for this purpose the Preparatory Commission shall make the necessary arrangements with the appropriate authorities of the United Nations, including arrangements for repayment of the loan by the Agency. Should these funds be insufficient, the Preparatory Commission may accept advances from Governments. Such advances may be set off against the contributions of the Governments concerned to the Agency.

C. The Preparatory Commission shall—

1. Elect its own officers, adopt its own rules of procedure, meet as often as necessary, determine its own place of meeting and establish such committees as it deems necessary;

2. Appoint an executive secretary and staff as shall be necessary, who shall exercise such powers and perform such duties as the Commission may determine;

3. Make arrangements for the first session of the General Conference, including the preparation of a provisional agenda and draft rules of procedure, such session to be held as soon as possible after the entry into force of this Statute;

4. Make designations for membership on the first Board of Governors in accordance with subparagraphs A-1 and A-2 and paragraph B of article VI;

5. Make studies, reports, and recommendations for the first session of the General Conference and for the first meeting of the Board of Governors on subects of concern to the Agency requiring immediate attention, including (*a*) the financing of the Agency; (*b*) the programmes and budget for the first year of the Agency; (*c*) technical problems relevant to advance planning of Agency operations; (*d*) the establishment of a permanent Agency staff; and (*e*) the location of the permanent headquarters of the Agency;

6. Make recommendations for the first meeting of the Board of Governors concerning the provisions of a headquarters agreement defining the status of the Agency and the rights and obligations which will exist in the relationship between the Agency and the host Government;

7. (*a*) Enter into negotiations with the United Nations with a view to the preparation of a draft agreement in accordance with article XVI of this Statute, such draft agreement to be submitted to the first session of the General Conference and to the first meeting of the Board of Governors; and (*b*) make recommendations to the first session of the General Conference and to the first meeting of the Board of Governors concerning the relationship of the Agency to other international organizations as contemplated in article XVI of this Statute.

ANALYSIS OF STATUTE OF THE INTERNATIONAL ATOMIC ENERGY AGENCY

1. The primary point of interest in the new statute is the composition of the Board of Governors of the agency.

The statute requires there to be a Preparatory Commission (annex I), composed of the following named countries:

Australia
Belgium
Brazil
Canada
Czechoslovakia
France
India
Portugal
Union of South Africa
Union of Soviet Socialist Republics
United Kingdom of Great Britain and Northern Ireland
United States of America

The following additional nations were chosen by the International Conference on the Statute of the International Atomic Energy Agency to be members of the Preparatory Commission:

Argentina
Japan
Egypt
Peru
Indonesia
Pakistan

This would make at least 13 out of 18 who certainly would be expected to be friendly to us.

The Board of Governors is selected from the members of the agency (art. VI). The initial membership of the Agency is composed of those states which are members of the United Nations, or of any of the specialized agencies which shall have signed the statute within 90 days after it is open for signature—or through January 24, 1957 (art. IV). Other members shall be those which accept the statute and are approved by the General Conference on the recommendation of the Board of Governors (art. IV).

The Board of Governors of the Agency is to have five members from those most advanced in the technology of atomic energy as designated by the Preparatory Commission or by the prior Board of Governors (art. VI). In addition, there are to be members representing those of the following areas which are not repesented by the first five members:

1. North America
2. Latin America
3. Western Europe
4. Eastern Europe
5. Africa and the Middle East
6. Southern Asia
7. Southeastern Asia and the Pacific
8. Far East

Next, two members are designated by the Preparatory Commission, or by the Board of Governors, from the following countries:

Belgium
Czechoslovakia
Poland
Portugal

One other member is to be designated as a supplier of technical assistance.

Lastly, 10 members are elected by the General Conference with an eye to equitable representation from the areas designated in the first list of areas, except North America. The members elected by the General Conference and designated by the Board of Governors under the latter two categories are not eligible for reelection in the same category in the following year.

The formula for establishing the membership for the Board of Governors is not as favorable to us as was the formula originally set forth in the draft statute of August 1955. It was recognized in the hearing last year that there would have to be further negotiations on the formula for the Board of Governors if, and when Soviet Russia decided to join in the International Agency.

The old proposal called for 5 members from the most important contributors of technical assistance and materials, 5 members from the most important suppliers of source materials, and 6 members to be elected by the General Conference. The provisions in the original draft practically provided for self-perpetuation of the original Board of Governors. This ability of self-perpetuation has been materially cut down in the statute.

It is to be noted that the description of the very first class of governors has been changed from "important contributors" of materials and technical assistance to those "most advanced in the technology of atomic energy."

At the Conference at the United Nations there was considerable discussion about possible changes in the composition of the Board of Governors. However, none of these changes was accepted. The Conference decided not to disturb the delecate balance which had been obtained on the structure of the Board of Governors.

2. The second important point which has been raised is the relationship of the Agency with the United Nations. The Board of Governors of the Agency is authorized to enter into an agreement with the United Nations and with any other organization whose work is related to that of the Agency (art. XVI). The agreement is to provide for reporting the activities of the Agency to the General

Assembly of the United Nations and also to the Security Council of the United Nations where there are questions which arise which are within the competence of the Security Council (also art. III). The Agency is also to submit reports to the Economic and Social Council and other organs of the United Nations on matters within the competence of those organs. In addition, the Agency is to operate in consultation with, and where appropirate in collaboration with, the competent organs of the United Nations.

3. The third major problem in the Agency is the problem of inspection and controls (art. XII). The Agency has the authority to approve the design of facilities constructed under arrangements with it, but such approval is solely to see the facilities will not further any military purpose and that it will comply with applicable health and safety standards and to insure the effective application of safeguards; to require adherence to health and safety measures prescribed by the Agency; to require the maintenance and production of operating records to assist in insuring accountability for source and special fissionable materials; to receive progress reports; to approve the means used in chemical processing and require the fissionable materials recovered to be deposited with the Agency until the member has peaceful uses for the material; to send inspectors into the states who have been designated by the Agency after consultation with the states; to have access to all information required for accounting for materials and to determine whether the materials are being used for peaceful purposes and in accordance with the health and safety measures; take corrective steps within a reasonable time, to suspend or terminate assistance and withdraw materials.

There was considerable pressure at the Conference to minimize the inspection and control clauses and to exempt source materials completely from the controls. Strangely enough, France appeared to join with India in this attempt. However, the attempt was stopped. The inspection and control clauses, as rewritten slightly, were accepted almost unanimously.

The staff of inspectors is specifically established in the statute. The reports of noncompliance are to go to the Director General who transmits the report to the Board of Governors. The Board calls on the states to remedy any noncompliance. Further noncompliance is reported to all members, to the Security Council, and to the General Assembly of the United Nations. The Board may curtail or suspend assistance, call for return of materials, and initiate proceedings to suspend membership.

The inspection and control procedures are to be made applicable not only to Agency projects but also to those projects sponsored under bilateral agreements between members of the Agency where both members request the Agency to take over the inspection and control. The inspection and control functions for the internal atomic energy program of any nation may be taken over by the Agency upon the request of that nation.

At the Conference many of the small nations requested that the inspection and control functions be limited by the sovereign rights of the nations inspected. The United States' answer, which effectively stopped this complaint, was that the very fact that a nation entered into an agreement with the Agency for assistance which required inspection and control was an exercise by the nation of its sovereign rights. Such an agreement did not abrogate the sovereign rights of the nation but constituted an exercise of them.

4. The fourth major point under the statute is the contribution of materials. Three months after the statute becomes effective with respect to any member the member is required to designate the amount of materials it may make available. This designation is to be made annually thereafter. Materials are to be contributed in such amounts as the member deems advisable and on terms as may be agreeable with the Agency (art. IX–A).

There is the requirement that—

> Each Member shall notify the Agency of the quantities, form, and composition of special fissionable materials, source materials, and other materials which that Member is prepared, *in conformity with its laws,* to make available immediately or during a period specified by the Board of Governors (art. IX–C).

Special fissionable materials made available may be stored by the member or, on agreement with the Agency, in the Agency depots.

5. The fifth major point is a question of financing. The budget of the Agency is divided into two parts—administrative and capital (art. XIV). With respect to the administrative budget, assessments can be levied against the members in accordance with the scale of the assessments, to be fixed by the General Confer-

ence, which is to be guided by the principles used by the United Nations in establishing its scale. The capital budget of the Agency is not to be assessable against any member but is to be made up either from gifts or from revenues other than assessments.

The Agency was specifically given authority to assist recipient nations on problems involved in obtaining financing from outside sources but the Agency cannot guarantee the financing or assume financial responsibility for any project (art. XI–B).

SUMMARY OF STATUTE

I. Establishes the Agency.

II. The objective is to accelerate the contribution of atomic energy to the peace, health, and prosperity throughout the world and to insure that assistance is not used for military purposes.

III. The Agency is authorized to encourage research on peaceful uses and to act as intermediary for having one member of the Agency supply services and materials to another; encourage the exchange of scientific information; to foster the exchange and training of scientists; establish safeguards for materials and services supplied by the Agency on request of those parties to a bilateral arrangement and to apply the safeguards to the bilateral; or, on the request of any nation, to the atomic energy program of that nation; establish health and safety standards; to acquire facilities, plants, and equipment. The Agency is required to conduct its policies in line with the policies of the United Nations to promote peace; establish controls over special fissionable materials received by the Agency; allocate its resources to insure efficient utilization and greatest benefit to all parts of the world: to submit reports on its activities to the General Assembly and to the Security Council where there are questions within the competence of the Council for the maintenance of international peace and security, and submit reports to the Economic and Social Council on matters within the competence of that Council.

Amendments to the statute to have the Agency publish a periodical, establish an international university, grant scholarships and convene international scientific conferences were not accepted by the Conference as all being included in the present powers of the Agency.

The Agency is forbidden from making assistance to members subject to conditions which are incompatible to the statute. The activities of the Agency are to be carried on with due observance of sovereign rights of states, subject to the statute and the agreements with the states which shall be in accordance with the provisions of the statute.

IV. Initial membership is limited to members of the United Nations and specialized agencies who sign within 90 days. Other members are to have approval of the General Conference on the recommendation of the Board of Governors but applicants are to be judged on their ability to abide by the principles of the United Nations Charter. The Agency is based on the sovereign equality of all members.

V. The General Conference of all members is to meet annually or in special sessions as called by the Director General at the request of the Board of Governors or the majority of members. The Conference is to elect a President and other officers. The majority is a quorum.

Decisions on the budget and financial questions, on amendments to the statute, and on suspension of membership for violation of the statute are to be taken by two-thirds of those present and voting. Other questions to be decided by a majority of members present and voting.

The General Conference may consider any matters within the statute. The functions of the General Conference are to elect governors; approve new members; suspend members from the privileges and rights of membership; consider the annual report; approve the budget or return it to the Board with its recommendations; approve reports to be submitted to the United Nations; approve any agreement between the Agency and the United Nations or other organizations; approve rules regarding borrowing powers of the Board; approve amendments to the statute; approve the appointment of the Director General.

The General Conference may make recommendations to the Board of Governors either relating to functions of the Agency or on matters brought to the attention of the General Conference by the Board. They may propose matters for consideration by the Board.

VI. Governors. (See initial analysis.)

In addition, the Governors designated by the prior Board of Governors or by the Preparatory Commission shall sit for 1 year but those elected by the General Conference shall sit for 2 years with 5 to be elected at each General Conference. Two-thirds of the Board of Governors constitute a quorum and the Board is to governed by majority rule. The Board is to elect a chairman, officers, and committees and is to prepare an annual report.

VII. The Director General is to be appointed by the Board of Governors, with the approval of the General Conference, for 4 years and is to be the chief administrative officer for the Agency. He is to be responsible for staffing and perform his duties in accordance with regulations adopted by the Board. The staff is to be kept to a minimum and shall be composed of qualified scientific and technical and other personnel as may be required. The paramount consideration is to secure employees with the highest standards of efficiency, technical competence, and integrity, otherwise to have as wide a geographical distribution as possible.

The Director General and staff are not to get instructions outside the Agency. Subject to the staff's responsibilities to the Agency, the staff shall not disclose industrial secrets or confidential information learned by reason of their official duties.

VIII. Members are to make information available which would be helpful to the Agency and to make all information available which is developed as a result of assistance extended by the Agency. The Agency is to assemble and make the information available among its members.

IX. Materials. (See initial analysis.)

In addition, the Agency is to be responsible for storing and protecting materials in its possession from weather, diversion, sabotage, and forcible seizure. In storing special fissionable materials the Agency is to insure geographical distribution so a large concentration will not go to any one part of the world.

X. Members may make services and other materials available.

XI. The member may request assistance of the Agency on any atomic energy project for peaceful purposes, the requests to be considered by the Board of Governors. The Agency may assist a member in obtaining financial assistance but may not make any guaranty or assume financial responsibility. The Agency may arrange for supplying materials and services by itself or one or more members. It may send qualified persons into the country to examine the request.

The Agency shall consider—

1. Usefulness of project.
2. Adequacy of plans.
3. Adequacy of health and safety standards.
4. Ability of member to secure necessary assistance.
5. Equitable distribution of sources available to the Agency.
6. Other relevant matters.

On approval of a project the Agency has to agree with the member on:

1. Allocation of materials.
2. Transfer of materials under conditions to meet health and safety standards.
3. The terms for the Agency supplying of materials and services.
4. Safeguards that the assistance will not further any military purpose and the project will be subject to further safeguards provided in the statute and in the agreement.
5. Appropriate provision for patent rights.
6. Appropriate provision regarding settlement of disputes.
7. Other appropriate provisions.

XII. Agency safeguards. (See initial analysis.)

XIII. Unless otherwise agreed, members supplying services and materials are to be reimbursed.

XIV. Finance. (See initial analysis.)

The Board of Governors is to submit an annual budget to the Conference. The expenditures are to be classified under administrative expenses, which include cost of staff and cost of implementing safeguards, and other expenses, including the costs of acquiring and operating plants used by the Agency in its authorized functions.

The Board of Governors is to establish a scale of charges including uniform storage and handling charges. The Board of Governors may borrow in accordance with the rules and regulations of the General Conference. Two-thirds of the General Conference and the Board of Governors must approve finance questions and the budget. The Agency may accept voluntary contributions.

XV. The Agency is to enjoy such privileges and immunities in the territory of each member which are necessary for its functions. Delegates and their staffs also enjoy such privileges and immunities as are necessary in the independent exercise of their functions. The legal privileges and immunities and capacity shall be defined in a separate agreement between the Agency, represented by the Director General, and the members.

XVI. Board, with approval of General Conference, may enter in agreements with the United Nations and other international organizations.

XVII. Disputes on interpretation or application of the statute may be referred to the International Court of Justice. The International Court may give an advisory opinion on request of the Board of Governors or of the General Conference.

XVIII. Amendments may be proposed by any member and are to be communicated to all members by the Director General at least 90 days in advance of consideration by the General Conference.

The agenda for the Fifth Annual General Conference after the statute becomes effective shall include the question of revision of the statute. The majority shall approve the review to take place at next General Conference.

Amendments shall come into effect when approved by two-thirds of the General Conference after consideration of the observations made by the Board of Governors and when considered by two-thirds of all members with respect to their constitutional processes.

At any time after 5 years from the date the statute goes into effect, or whenever an amendment unsatisfactory to the members is accepted, the member may withdraw. The member may be suspended if it is in arrears in its dues in an amount equal to more than the dues of the last 2 years.

XIX. Two-thirds of the members may vote to suspend a membership if the member is persistently violating the statute, or is 2 years behind in financial contributions.

XX. Defines "special fissionable material," "Uranium enriched in isotopes 235 and 233" and "source material."

XXI. Sets the date when the statute is open for signature and has the period of signature run for 90 days. The signatory parties become parties to the statute by the deposit of an instrument of ratification. The Government of the United States is designated as the depository government. Ratification or acceptance is to be effected by the States under their usual constitutional processes and becomes effective when 18 States have deposited instruments of ratification (including 3 of "Big Five" nations named). The depository government is to notify all states of the date of deposit of ratification.

XXII. The statute and the agreements entered into by the Agency are to be registered with the United Nations in accordance with the terms of the article 102 of the charter.

XXIII. Sets forth that the authentic texts are in Chinese, English, French, Russian, and Spanish.

ANNEX I. PREPARATORY COMMISSION

The membership of the Preparatory Commission has been set forth in section I. The expenses are to be met by a loan from the United Nations which is to be paid out of assessments of members of the Agency. The Preparatory Commission is empowered to elect its officers; appoint an Executive Secretary and staff; arrange for the first session of the General Conference; designate members of the first Board of Governors in accordance with the statute; and report to the first General Conference on—

1. The financing of the Agency.
2. The Agency programs and budgets for the first year of the Agency.
3. The technical problems of the Agency.
4. Establishment of a permanent staff.
5. Location of permanent headquarters.

It is also empowered to recommend provisions for a headquarters agreement, to negotiate a draft agreement with the United Nations, and to recommend to the General Conference concerning the relationship of the Agency with other international organizations.

DEPARTMENT OF STATE,
Washington, June 4, 1957.

The Honorable J. W. FULBRIGHT,
Committee on Foreign Relations,
United States Senate.

DEAR SENATOR FULBRIGHT: Your subcommittee has asked for clarification of certain testimony given by representatives of the Department of State and the Atomic Energy Commission during the course of the Senate Foreign Relations Committee hearings on the statute of the International Atomic Energy Agency and on the policy to be pursued in connection with United States participation in the Agency. I am glad to provide this clarification.

It has been asked whether the statute of the International Atomic Energy Agency, if ratified by the United States, would supersede the procedures for the transfer of special nuclear material required by the Atomic Energy Act of 1954, as amended. It would not. Section 124 of the Atomic Energy Act and related sections 123 and 54 would govern the transfer of special nuclear materials to the Agency, including the 5,000 kilograms of U–235 which the President offered to make available to the Agency last October. The United States cannot, under the terms of the Atomic Energy Act, transfer materials to the Agency until the conditions of the Atomic Energy Act are met, including the following: (1) The Atomic Energy Commission has submitted to the President a proposed agreement for cooperation with the Agency, including among other provisions the terms of the transfer of materials to the Agency; (2) the President has approved and authorized the execution of the agreement after making a determination in writing that the performance of the agreement will promote, and will not constitute an unreasonable risk to, the common defense and security; and (3) the proposed agreement has been submitted to the Joint Congressional Committee on Atomic Energy and the period of time prescribed in the act has elapsed. It should be noted that article IX (C) of the statute of the International Agency provides that any member making materials available will do so in conformity with the laws of that member state.

It has also been asked whether amendments to the statute would be submitted to the Senate for advice and consent to ratification. I can assure you that this would be the case. Amendments to the statute come into force for all members only after they have been accepted by two-thirds of them in accordance with their respective constitutional processes. However, the interests of the United States are protected since it would have the right provided in article XVIII (D): "Whenever a member is unwilling to accept an amendment to the statute it may withdraw from the Agency by a notice in writing * * *" There have been questions as to whether the President would act to effectuate withdrawal of the United States from the Agency if the Senate did not consent to the ratification of an amendment that had been accepted by two-thirds of the members of the Agency. We believe that he would and should do so if a majority of the Congress were of the view that the amendment so altered the nature of our treaty obligation as to render our continued participation in the Agency inconsistent with the interests of the United States. However, in my opinion, and as I said in my testimony before the Senate Foreign Relations Committee, the participation of the United States is so vital to the existence of the Agency that I cannot visualize a situation in which an amendment would be ratified by two-thirds of the members of the Agency that would impair or endanger the continued wholehearted support of the United States.

The subcommittee has asked whether the statute is self-executing and whether implementing legislation is needed to enable the United States to participate in the Agency. Effective United States participation will require three types of legislation: (1) The existing Atomic Energy Act of 1954; (2) a participation act; and (3) annual appropriations.

The internationally binding character of the limited obligations contained in the statute is, of course, not conditioned on the enactment of legislation by the governments of Agency members. Within the United States, the payment of this country's share of the administrative expenses of the Agency will require both authorizing legislation and annual appropriations by the Congress. However, the other obligations contained in the statute of the Agency (to act as depositary, to afford the Agency certain limited privileges and immunities) do not require implementing legislation.

To cover the administrative details of United States membership in the Agency, a draft participation act has been submitted to the Congress; a copy of this legislation is attached. It will provide for the appointment of United States representatives to the Agency and authorize the appropriation of funds needed for United States participation.

It should be reemphasized that nothing in the statute of the Agency obligates the United States to provide materials, equipment, or facilities to the Agency. As article IX states, the furnishing of special nuclear and other materials is to be in conformity with the laws of each member. For the United States, this means the Atomic Energy Act of 1954, as amended, which already provides procedures for cooperation with the International Atomic Energy Agency. There is no conflict between the statute of the Agency and the United States Atomic Energy Act.

During the course of my testimony there were inquiries as to whether the United States would donate the special nuclear material we make available to the Agency and its projects. Article IX provides that material shall be made available on terms to be agreed with the Agency. Article XIII provides that supplying governments will be reimbursed by the Agency for such materials unless otherwise agreed. The intention and policy of the United States Government is to apply the principles now prevailing for the bilateral program which require reimbursement for the cost of special nuclear materials except in special instances when limited quantities may be transferred for research or medical purposes. If future developments should make a basic change in policy with respect to donation desirable and in the interests of the United States, appropriate congressional approval will be sought.

A question has also been raised as to what steps can be taken to encourage other governments to make material available to the Agency. In our judgment, the initial United States offer of a substantial quantity of special nuclear materials constitutes an earnest of our desire for an effective Agency and, as such is the best method of encouraging substantial offers from other countries. The scope and degree of our further support for the Agency will be decided upon, of course, in the light of the cooperation given by other governments. While the furnishing of material by any member of the Agency is entirely voluntary, the United States hopes and expects that cooperation will be forthcoming and will use its best efforts to encourage wholehearted support of the Agency by its members to the extent of their capabilities.

While only 2 or 3 countries are now in a position to sell, lease, or otherwise make available special nuclear materials, other countries could make available equipment and other useful materials, such as natural uranium which is also a reactor fuel. When the Agency, in accordance with the provisions of article IX (B), has determined its needs for such materials, facilities, and equipment, we are confident that these countries will make offers to supply them. In fact, once the Agency has been established and its safeguards system is in force, its members will have an incentive to use the Agency as a channel for marketing nuclear materials.

Questions have been raised with regard to the extent and nature of the United States commitment to deliver special nuclear material to Agency projects or to the Agency itself. Can the United States be required to deliver materials before there is need for their use in approved specific projects? Will ratification of the statute commit the United States to deliver special nuclear materials to the Agency without prior knowledge of the projects to which these materials will be allocated?

The United States presently has no legal commitment to deliver any material to the Agency. We plan to carry out the President's offer of 5,000 kilograms of U-235 plus a sum equal to all quantities of such materials made available by other nations prior to July 1, 1960, subject to an agreement being concluded with the Agency on the terms and conditions under which it will be made available in accordance with the Atomic Energy Act of 1954, as amended. After such an agreement has been concluded, the Agency may request delivery of specific quantities of this material as it is needed for specific projects which have been approved by the Board of Governors or for use by the Agency itself. Until that time, the United States will retain special nuclear material made available to the Agency within its own boundaries.

No member has the right to designate the specific projects in which the material made available to the Agency will be used. However, the United States, through its membership on the Board of Governors, will have full knowledge of

the Agency's projects and programs when we reach decisions in the future on amounts of material which we may subsequently make available to the Agency. Our decisions will be guided by our judgment of the needs and policies of the Agency and the security interests of the United States. Even with respect to the 5,000 kilograms, the United States will have ample opportunity beginning with the initial application for an Agency supported project, to be informed of the circumstances surrounding a proposed project and to be assured that the principles and objectives of the Agency are respected.

We were asked to clarify the interpretation of the word "terms" in the light of the negotiating history of the statute. The word "terms" as used in article IX (A) of the statute is not limited by the negotiating history. In our interpretation the word "terms" means "terms and conditions." It will be our policy to include in any agreement with the Agency under article IX (A) of the statute a provision that no materials will be shipped from the United States until they are needed for specific projects approved by the Agency. The Agency could not, of course, properly agree to the inclusion of any conditions in such agreements that were in conflict with any provision of the statute. For example, it could not agree to a term in such an agreement that was inconsistent with the provision in article IX (J) that "No member shall have the right to require that the materials it makes available to the Agency be kept separately by the Agency or to designate the specific project in which they must be used." In the case of the United States, special nuclear materials cannot be made available to the Agency except in conformity with an agreement for cooperation negotiated under the provisions of the Atomic Energy Act of 1954, as amended.

For purposes of evaluating the President's offer, it may be noted that 5,000 kilograms is approximately the amount of U–235 required to fuel 2 or 3 medium-sized reactors throughout their useful lives. Moreover, the degree of enrichment of this uranium will be far below the level required for weapons-grade materials. As Chairman Strauss of the Atomic Energy Commission has testified, the United States will not supply the Agency with material enriched in excess of 20 percent.

Some questions were also raised concerning the dividing line between administrative and other expenses. Article XIV (B) (1) of the statute, entitled "Finance," identifies those expenses which may properly be included in the administrative budget. Furthermore, it is the accepted practice in international organizations in which the United States participates to confine administrative expenses to those which are for general support, such as salaries of the Secretariat staff, conference or meeting costs, travel, etc. Also included in administrative expenses are costs of implementing safeguards for Agency projects and certain costs related to the handling of Agency materials. In the light of the provisions of article XIV (B) (1), and of the practice followed generally in international organizations, the Agency's administrative budget will not include or provide for physical facilities such as reactors or "universities." Such expenses would be financed by charges voluntarily agreed to by members benefiting from the projects concerned, and should the United States decide to participate therein the United States dollar share of these amounts would have to be authorized and appropriated.

Finally, a question often asked was whether we are contemplating furnishing the Agency classified information. No secret or classified information will be provided to the Agency.

Sincerely yours,

JOHN FOSTER DULLES.

Senator PASTORE. Now, I take it from the experience we have had on the ratification of the statute itself that the part that needs to be crystallized in the record at this point and comprehensively and intelligently explained, is this feature of control of the material that is furnished by the United States to the agency itself, with particular reference to section 124, section 123, and section 54 of the Atomic Act of 1954.

All this was pointed up emphatically and vividly by the proposed reservation that was suggested by the distinguished Senator from Ohio, Mr. Bricker.

I think we ought to develop the record on that particular point very extensively and very clearly for the understanding of Members of the Senate and Members of the House.

If there are any questions, Senator Bricker, you may proceed.

Representative COLE. Before you proceed, Mr. Chairman, may I interrupt for a moment to call to your attention the presence of a member of the Japanese Diet, who is also interested in atomic energy and who is visiting this country for a short while, Mr. Saito. I wonder if he will stand so that the members of the committee might see him.

Senator PASTORE. We are very happy to have you here today.

Senator BRICKER. I have only a question or two.

First, of Secretary Wilcox: You mentioned on the first page of your testimony that the proposal of the President and this organization was greeted with great enthusiasm throughout the world. Will you furnish for the record any statements or communications which underlie that statement?

Mr. WILCOX. I shall be glad to do that, Senator.

(The material referred to follows:)

STATEMENT ON WORLDWIDE REACTION TO PRESIDENT EISENHOWER'S PROPOSALS FOR AN INTERNATIONAL ATOMIC ENERGY AGENCY

At the close of the 8th session of the U. N. General Assembly, on December 3, 1953, President Eisenhower announced his "Atoms for Peace" proposal, including the suggestion that an International Atomic Energy Agency be established.

This proposal was not formally discussed by the General Assembly until its 9th session in the fall of 1954. At that time many delegations warmly commended the President's initiative. General Assembly Resolution 810 (IX), which was adopted unanimously, included the following: "Recalling the initiative of the President of the United States of America, embodied in his address of December 8, 1953 * * * Expresses the hope that the IAFA will be established without delay * * *"

Less than 2 years later, the Conference to draft the International Atomic Energy Agency Statute was convened at the United Nations. It was attended by representatives of 80 states and 7 specialized agencies. At the conclusion of the Conference, the statute was unanimously approved, and 80 states subsequently signed the statute.

This record of unanimity in voting is probably the best indication of the great and universal appeal of the President's proposal. As further evidence of the great acclaim accorded the President's proposals, I am submitting the official records of the opening debate in Ninth Session of the General Assembly. If the committee so desires, I will be glad to supply the complete and voluminous verbatim records of the Ninth General Assembly, both of the plenary and first committee meetings, and the summary records of the October 1956 IAEA Conference. The many speeches in praise of the President's proposal contained in these records are further proof of the enthusiasm with which the world received the President's proposals.

Senator BRICKER. Then on page 5 you say appropriate officers of both agencies will be available on request to furnish information and answer questions.

There will not be any requirement in this statute, as I understand it, which would require the agency representatives of the United States to keep this committee currently informed of all the developments.

Mr. WILCOX. No, sir; there is not any specific language except on page 4, where it provides that the President shall from time to time as the occasion may require make reports to the Congress, and so on.

But there is no specific language that requires informal consultation. Certainly it is the desire of the executive branch to keep the members of this committee and other interested committees informed of major

developments and we shall be glad to do that in any way that the committee would deem appropriate and desirable.

Senator BRICKER. Would there be any objection to putting into this statute a requirement such as in the Atomic Energy Act that this committee be kept currently advised of all developments?

Mr. STRAUSS. Might I respond to that?

Senator BRICKER. Yes.

Mr. STRAUSS. I think, Senator Bricker, that the obligation of the Atomic Energy Commission to keep the joint committee fully and currently informed would certainly apply to any information that reached the Atomic Energy Commission.

Senator BRICKER. There is no doubt about that.

Mr. STRAUSS. And since no material could be provided or anything involving the Atomic Energy Agency be agreed upon without our knowledge, I think the joint committee could under those circumstances expect to be fully and currently informed.

Now, an obligation placed by an amendment to this act on the Secretary of State, I think would involve a duplication of information, that is all.

Senator BRICKER. There would be no objection, if there were certain areas in which there would be information of value to this committee to be furnished by the Secretary of State, that that be put in the statute.

Mr. STRAUSS. I see none except the fact of duplication.

Chairman DURHAM. Do you not think section III covers that?

Senator BRICKER. That was my question if it did. I am so advised it did not except the President's annual report.

Chairman DURHAM. Reading the language I believe it will cover that.

Senator BRICKER. I wanted to get the attitude of the State Department in regard to that.

Chairman DURHAM. That provision is set forth in the original statute in 1954.

Senator BRICKER. Mr. Wilcox said they felt there was no obligation except the annual report to the President.

Chairman Strauss said there was no obligation except the Commission must reveal to us fully and currently all information which it receives.

And it would receive, as he says, the information in regard to the supply of material which would be, of course, presented to us immediately.

Mr. STRAUSS. I have this further observation, that just occurs to me. If there is a provision in this participation act that places the responsibility on the State Department to keep the Joint Committee informed of these negotiations and the Commission is relieved, let us say, to that extent, there is the possibility that in both agencies the presumption might arise in some matter that the other agency is informing the Joint Committee.

I would assume, were I otherwise situated, that you will get a more consistent line of information if the responsibility is in one direction, to 1 agency, rather than to 2.

Senator BRICKER. I would feel it would be just as consistent and achieve my objective as well if we placed that obligation on the Atomic

Energy Commission and that they be currently advised by the State Department of all developments.

What I am thinking about is a complete story of the development of atomic energy and the peaceful uses particularly.

Now, we are a great repertory in this committee of both classified and unclassified material. Certainly here is a field of great development, the magnitude of which we do not yet fully understand.

I think there ought to be a current history and story of the whole development some place that future generations might go to as an account of just what has been accomplished.

Mr. STRAUSS. The Commission appointed a historian, I think just a few days ago, with that as one of its primary responsibilities. I don't claim any clairvoyance, Senator Bricker, in reading what was in your mind, but we thought it was a desirable thing to do.

Senator PASTORE. If I may say a word or two on the same subject, I should think that possibly some desirable language could be agreed upon between our staff and the representatives here to carry out that very thought which is quite an important one, namely to keep the Congress and the people of the United States apprised and informed currently, within reason, as to how this thing develops, which is quite important.

But the one thing we must bear in mind, and that we must be careful about, is the language, because, first of all, our representatives there will be under the instruction of the President, himself. They will be able to do nothing unless they are so instructed by the President of the United States, as they do at the United Nations.

Therefore, whatever is done there will have to be done, of course, under the direction of the President.

The question arises, we must not encumber the President to the extent he does not have the flexibility and fluency he needs to carry out his executive responsibility in this premise.

On the other hand, it strikes me that once thees things have been done, something could be worked out whereby the Joint Committee would be kept constantly and currently informed as to the developments as we do with the liaison between the Commission and the Joint Committee.

I see no hardship here and I think that that can be worked out without tying the hands of the President so that he can be a free agent without having to report on every little instruction that is given out to the Agency in the conferences as to what we should do or should not do.

Senator BRICKER. I had no thought of covering that.

Senator PASTORE. I realize that.

Senator BRICKER. What I had in mind is that we be currently advised of our representatives' activities. He may be instructed by the President, but his instructions by the President may not be carried out by the Board of Governors.

I want all the official actions insofar as we can ascertain them presented to this committee so that there will be a continuity of the story fully developed.

Mr. STRAUSS. Mr. Chairman, may I read something that perhaps will be very reassuring along this line? This is a letter dated the 27th of May from the Secretary of State to the Speaker of the House

of Representatives. I assume that there was an identical letter written to the President of the Senate. I don't have a copy of it.

In this letter in the third paragraph the Secretary of State says:

> To direct United States participation in the work of the Agency regular procedures are being established within the executive branch for coordination and collaboration between the Department of State and the Atomic Energy Commission in the determination of positions to be taken by the United States in the organs of the agency and for obtaining recommendations regarding the policies to be followed by the United States in the course of its participation.

These procedures will make the Atomic Energy Commission aware of and a participant with the Department of State in these instructions and in this information and will provide the Commission with that information which it is duty bound to convey to the Joint Committee fully and currently.

Senator PASTORE. In order to bring this to a head, is there any objection in working out language that will carry out the thought expressed by Mr. Bricker. Does anyone see any disadvantage to that suggestion?

Mr. SMITH. It seems to me under section 202 of the Atomic Energy Act of 1954, you have the machinery that Senator Bricker is looking for. That requires any Government agency to furnish any information requested by the Joint Committee on the responsibilities of that agency in the field of atomic energy.

If you, under that section, will just lay a charge on us in the State Department to keep you fully and currently informed of all activities in the International Atomic Energy Agency, we will respond willingly.

Senator PASTORE. Do you see any harm in codifying it in this?

Mr. SMITH. No, sir.

Senator BRICKER. Of course, that will put the responsibility then where it belongs and it will not necessarily be on the Joint Committee.

Mr. WILCOX. Mr. Chairman, while the Department would recognize the deep interest of this committee in this subject matter, I don't think we would want to include such language that might imply that we were not interested in keeping the Foreign Relations Committee of the Senate or the House Foreign Affairs Committee informed of important political aspects of the atomic-energy field.

Senator PASTORE. You can say the appropriate committee. We can work out that language. That is merely mechanical.

Naturally, of course, we mean every pertinent committee interested in the functioning of this International Agency.

Senator BRICKER. I have one further question, Mr. Wadsworth, has there been a schedule of payments to the Agency yet made up? You note here there will be $2,300,000 of the United States share, not to exceed one-third. Has the schedule been made up for the contributions of the other members of the Agency?

Mr. WADSWORTH. No, the schedule is not. The reason why that one-third was in the statement is the idea it will follow more or less the United Nations practice and the United States share of the United Nations administrative expense is one-third.

Now, if the Congress and the Senate did adopt such an amendment, as they did 2 years ago, limiting the United States contribution to 25 percent on all the International Agencies, do you think that would be

a violation of the treaty and our obligations under it if such should become the law of this country?

Mr. WADSWORTH. That is a legal question, sir, that I am afraid I am not competent to answer.

Mr. WILCOX. If I can address myself to that rather obliquely, Senator Bricker, as you know, we are now contributing 33⅓ percent to the regular United Nations budget. The contributions which we make to many of the specialized agencies of the United Nations are determined by the pattern set by the contributions committee of the United Nations proper.

In the statute there is a provision that the principles which apply to the contributions scale in the regular United Nations budget should apply here.

In the light of the new membership in the United Nations, we are attempting to bring our contributions down below the 33⅓-percent ceiling.

The Congress could, of course, insert here a proviso to the effect that we ought not to contribute more than 25 percent to this Agency, but we would run into difficulty, because my assumption is that this Agency would determine its scale in accordance with the scale of the United Nations and they would suggest our contribution at the 33⅓-percent level until that contribution is reduced in the negotiations that will take place in the next year or so.

We would get into serious complications in our attempt to reduce all of our contributions to the various United Nations agencies. I did not mean to answer the legal problem.

Senator BRICKER. You do not mean to infer that the control of the contribution is out of the hands of Congress at all?

Mr. WILCOX. Well, of course, the executive branch is constrained by any action that the Congress would take with respect to our contributions. I think that we might find that it would constitute something of a violation of our obligation under the statute. I think the more effective way to go about it would be to press for a reduction of our contribution to the regular United Nations budget and then get a corresponding reduction in this Agency and in other specialized agencies of which we are a member.

Senator BRICKER. My question does not go to the matter of policy. It goes to the question of power and whether or not we are getting the appropriation authority out of the hands of the Congress of the United States, which is clearly ours under the Constitution.

My question is whether or not in your judgment the ratification of this treaty takes that appropiration power away from the Congress.

Mr. WILCOX. No, sir; I don't think it takes it away from the Congress. I think the statute lays down a reasonable basis for contributions. I think you will agree, Senator Bricker, that if each state were to determine for itself the amount of money that it could contribute to the regular budget of this Agency, you would have nothing but financial chaos because each state would attempt to reduce its contribution to the very minimum it could possibly get by with.

Therefore, you do have to have some kind of systematic approach to a determination of the fiscal, financial arrangements of an agency of this character.

Senator BRICKER. I grant you it might be very unwise for us in any way to vary what was allocated to us as a charge within reason

and yet I am trying to get to the question of whether or not the power here is taken away from the Congress to fix the amount of our contribution to this Agency.

Mr. WILCOX. No, sir; I don't think it is. I think we enter voluntarily into an arrangement which is a reasonable arrangement. I don't think that is a restriction of the power of the Congress.

I think that Congress can, if it wishes, proceed to appropriate less than 33⅓ percent. It can appropriate, as it did in the case of the International Labor Organization, appropriate less than that amount which was fixed by the conference of the Internatioal Labor Organization for our contribution. But it does ot result in a very happy arrangement, nor does it create good will or good relations as between the Untied States and the other members of the organization.

Senator BRICKER. I see now they are having trouble further with the Hungarian representatives.

These nonrecurring items mean that the United States will have paid all of the cost of the preparatory program, the cost of the agency which drafted this statute.

Mr. WADSWORTH. No, as I understand it, the costs will be apportioned among the 18 members of the Preparatory Commission in the first instance, but that the money which has been advanced by the Secretary General of the United Nations must be repaid to the United Nations by the Agency itself, not by the individual countries. So that that will be a nonrecurring cost in the Agency's first year budget.

Then we will, thereafter, have one-third of that.

Senator BRICKER. Our proportionate share?

Mr. WADSWORTH. That is correct.

Senator PASTORE. Now, on this point that was raised by Senator Bricker, do I understand it correctly when I say that regardless of what the agreement may be as to the Agency, as to the amount of money we will contribute as our share, that will have to be submitted as an estimate on the part of the Bureau of the Budget every year, as we appropriate all money and the final decision as to the dollars and cents to be contributed will be the responsibility of Congress predicated upon whatever agreements have been made by the executive branch.

Mr. WILCOX. That is correct.

Senator PASTORE. It is not a question of abrogation at all. It is a question that the final decision will always remain in the Congress as we do with foreign aid and as we do to all appropriations to Government agencies.

Mr. WILCOX. That is correct. Each year the executive branch comes before the Congress with the request which it would like to put before it in connection with our participation in these various agencies and it is up to the Congress to determine.

Senator PASTORE. To decide the dollars and cents to be contributed?

Mr. WILCOX. That is correct.

Senator BRICKER. I am the last one to ever think of the United States violating its obligations under an international agreement which has been entered into. The same thing goes for this.

I just wanted to lay the foundation of what we were obligated to do in the future in order to carry out the provisions of this treaty, whether a reduction of our contribution would be a violation of our obligations, which is a very serious matter to me in international law.

Senator PASTORE. Has not our obligation been spelled out in the treaty that we have already ratified?

Mr. WILCOX. That is correct.

Senator PASTORE. Congress has already ratified the statute which sets out the principle by which we have made our contribution. How that principle is worked out is still a matter to be decided between the executive branch and the Appropriations Committee.

Mr. WILCOX. Mr. Chairman, article XIV does set forth the method by which the Board of Governors shall apportion the expenses and the method by which the General Conference shall approve the estimates submitted by the Board of Governors.

It provides specifically that in fixing the scale the General Conference shall be guided by the principles adopted by the United Nations in assessing contributions of member states to the regular budget of the United Nations.

Now, our purpose in seeking this kind of language was to make certain that our contributions should not exceed the 33⅓ percent ceiling which we have been working toward in all these agencies.

We have been getting it down to that level. We wanted to make certain there would be no attempt on the part of the member states to get us above that ceiling of 33⅓.

If, in the meanwhile, our contributions to the regular budget can be reduced below the 33⅓, then automatically it would be reflected because of the application of article XIV, paragraph D of the statute.

Mr. STRAUSS. Mr. Chairman, may I offer an observation here.

Unlike many other international bodies this Agency will be in a position, it is hoped, to recoup a large part of its expenditures, if not all, by the price at which it will resell the material which it purchases from the nations that supply it.

There is no reason that this should continue to be a drain on the participating countries except insofar as the pay of the representatives of the countries to the board and other administrative expenses are involved.

I would hope that that would be a situation that could be reached after a few years of operation.

Senator PASTORE. On October 26, 1956, the President of the United States, through Admiral Strauss, made the concluding speech at the negotiating conference for the establishment of this International Agency. This was read by Mr. Hickenlooper on the floor of the Senate when we discussed and debated the treaty.

I want to read it at this time because I think there are certain pertinent questions that should be cleared:

> Here is what I, on behalf of the United States, propose

says the President:

> First, It shall be my care, when our Congress reassembles, to present the statute for official ratification by the Senate in accordance with our Constitution, and to request appropriate congressional authority to transfer special nuclear materials to the International Atomic Energy Agency. I wish my country to be among the first to recognize by official action what you at this Conference have accomplished.
>
> Second, to enable the International Atomic Energy Agency—upon its establishment by appropriate governmental actions—to start atomic research and power programs without delay, the United States will make available to the International Agency, on terms to be agreed with the Agency, 5,000 kilograms of the nuclear fuel uranium 235 from the 20,000 kilograms of such material

allocated last February by the United States for peaceful uses by friendly nations.

Third, in addition to the above-mentioned initial 5,000 kilograms of uranium 235, the United States will continue to make available to the International Atomic Energy Agency nuclear materials that will match in amount the sum of all quantities of such materials made similarly available by all other members of the International Agency, and on comparable terms, for the period between the establishment of the Agency and July 1, 1960. The United States will deliver these nuclear materials to the International Agency as they are required for Agency-approved projects.

Now, there are several questions that I should like to ask and I know that there are certain questions that Mr. Bricker, Mr. Hickenlooper, and other members, would like to ask also.

What was meant when the President said: "By appropriate congressional action," with reference to the 5,000 kilograms?

Mr. STRAUSS. That, Senator, referred to the language in the act in section 124, which is short and which I will read for the record, with your permission:

The President is authorized to enter into an international arrangement with a group of nations providing for international cooperation in the nonmilitary application of atomic energy and he may thereafter cooperate with that group of nations pursuant to sections 54, 57, 64, 82, 103, 104, or 144a: *Provided, however,* That the cooperation is undertaken pursuant to an agreement for cooperation entered into in accordance with section 123.

That section 123, the preceding section, specifies all the terms which the Commission has adhered to in the negotiation of bilateral agreements, a number of which have already been laid before your committee.

Senator PASTORE. In other words, in order to crystallize the record at this point, what was meant by the President on October 26 was precisely this: That insofar as the availability of the 5,000 kilograms is concerned we will have an agreement that will come here which will rest with the joint committee for a period of 30 days, upon which it will become consummated as a binding agreement.

Mr. STRAUSS. Precisely.

Senator PASTORE. In other words, the President of the United States will have exclusive authority under sections 124 and 123 to make available this 5,000 kilograms of U–235 which will become a consummated agreement after that arrangement has come before the Congress for a period of 30 days and if the Congress desired to do anything about it it would have to initiate legislation for the repudiation of that agreement.

Mr. STRAUSS. That is my understanding.

Representative COLE. On that point, I want to make certain that I understand Mr. Strauss' response.

By that do I understand you to indicate that if the President desires to give 5,000 kilograms to the International Agency, he may do so simply by way of the bilateral agreement under 123?

Mr. STRAUSS. Mr. Cole, in the course of testimony which I gave before the Senate Foreign Relations Committee on May 14, in reference to some representations that have been made in the press to the effect that the 5,000 kilograms or some portion thereof was intended as a gift, I said that—

The United States has not offered to make a gift of the materials to the Agency. The President's statement explicity referred to terms to be agreed

upon and that articles IX, XI, and XIII of the Agency statute likewise provide specifically for reimbursement.

and I added that—

In any event, the advice and authorization of the Congress would be specifically sought before any gift was made to the Agency or to any nation or group of nations should such a gift appear advisable at some future date.

Representative COLE. That hardly answered my question.

Mr. STRAUSS. It was intended to; I am sorry.

Representative COLE. Do you construe the present status of the law and the treaty to authorize the President to make a gift to the International Agency of this nuclear material solely by way of the bilateral agreement?

Mr. STRAUSS. Mr. Cole, I believe if there was a bilateral agreement which envisaged a gift and it was submitted to the Congress and that no action was taken by the Congress to——

Senator HICKENLOOPER. To the Congress or the joint committee?

Mr. STRAUSS. The joint committee. I speak of the joint committee, Senator Hickenlooper, and the Congress, perhaps erroneously, as one in this case—that if the joint committee took no action to change that course of events it would be a gift.

Representative COLE. Is it not a fact that the Commission has previously interpreted that section of the act authorizing the distribution of nuclear fuel abroad to limit them in such fashion that that the Commission is limited to sale?

Mr. STRAUSS. I beg your pardon, sir?

Representative COLE. Has not the Commission previously indicated to the joint committee that its interpretation of that section of the statute which authorizes the Commission to distribute nuclear materials abroad does not include authorization by way of a gift and that the Commission is limited to sale?

Mr. STRAUSS. Or transfer. Here is a letter writen by the Commission, Mr. Cole, on February 15, 1957, on this point.

DEAR SENATOR PASTORE: Please refer to the letter of January 5, 1957, from you and Senator Anderson requesting the views of the Commission as to its authority under the Atomic Energy Act of 1954, as amended, to make a gift of special nuclear materials without direct congressional action. Section 54 of the act authorizes the Congress to cooperate with any nation by distributing special nuclear material and to distribute such material subject to the terms of an agreement for cooperation to which such nation is a party. The General Counsel of the Commission advises that examination of other sections of the act and the legislative history does not reveal that the precise method of transfer—that is to say, by sale, lease, or gift—was specified.

Congress wisely permitted a degree of flexibility as to the means of transfer. Thus the Commission in fulfilling its statutory responsibilities to foster research and development on the peaceful application of atomic energy could, for example, make modest gifts of special nuclear materials for use in research under an agreement for cooperation made in accordance with section 123 of the act, as amended. It is the General Counsel's view, however, that the act does not clearly provide authority for a gift of special nuclear material involving substantial quantities and large sums of money.

Accordingly, the General Counsel has advised the Commission that should it wish to provide for a gift of a substantial quantity of special nuclear material in an agreement for cooperation entered into under the Atomic Energy Act of 1954, as amended, explicit congressional authority should be obtained.

The Commission does not presently have any such proposal before it.

Senator PASTORE. That is a statement of policy. That is not a statement of law. But insofar as the law itself is concerned under

section 54 of the amendment of 1954, the President of the United States, through a bilateral with this International Agency, if he so chose, could give it away.

I would like to get an answer "yes" or "no" on that and point up the part of the law that answers that question, because we have skirted all around that issue and we come down to a question of policy as against law.

Now, we are not talking about what the policy is. We are talking about what the law is.

Mr. STRAUSS. At that time, Mr. Chairman, the General Counsel's view was that the act and the legislative history were not clear. It was his view, however, that the act does not provide authority for a gift without specific congressional authority.

Senator PASTORE. He said for a large amount. But for a small amount the act does. It cannot be one law if you give a little and another law if you give a lot unless you say so.

I mean the quantity does not measure the authority of the law. That is the opinion we have gotten and we are a little confused with it.

Now, let me ask this question, if I may:

What would be the disadvantage to us and to the agency and to the negotiators if we wrote into this implementation act that any amount that is given to the Agency or any material cannot be given on terms less favorable at the time to domestic recipients?

What is wrong with that? Where is your disadvantage?

I would like to have that thrown out on the table and the record made clear.

Why can we not write in this act that you cannot give to a foreign nation under terms less favorable than to domestic recipients any amount of special nuclear material? What is wrong with that?

This is for power purposes. We are not talking about medical research. I am not getting into medical research.

Mr. STRAUSS. That small amount is significant in terms of dollars.

Senator PASTORE. What would be the objection in writing into this implementation legislation that whatever is given must be given on terms that are not more favorable than you are willing to give to American recipients?

Mr. STRAUSS. Would it not be preferable to write into the legislation at some appropriate point that there is no gift of special nuclear materials without specific congressional authorization, which is what the President has indicated he would request in any event?

Senator PASTORE. You are willing to compromise to this extent. Now, we have to think this through deeply. You are willing to have written in here that before the President can give it away he must come to Congress to get that authorization?

Mr. STRAUSS. I would be, yes. I would like to give my associates an opportunity to join or differ with me in that position, but speaking personally, I would think that is a proper thing, since it only gives effect to something that the President has already said he intends to do.

Representative COLE. To me it is important to know what you understand when you say specific congressional authority. Are you referring to authority by way of the bilateral agreement method, or are you referring to specific language in the statute?

Mr. STRAUSS. Well, at the present time, Mr. Cole, it does refer to the bilateral agreement method in sections 123 and 124.

Representative COLE. But the interpretation of your counsel says that if the Commission feels that the material should be given by way of an international agreement, bilateral agreement, explicit congressional authority should be obtained.

Of course, he is not here; we cannot explore his mind to determine what he had intended when he said: "Explicit congressional authority."

I had understood him to interpret that to mean that the basic law would have to be revised to authorize the President to make gifts, supplemented later on by way of bilateral agreement.

Senator BRICKER. Mr. Chairman, a further question arises at what point it becomes a gift. What would be the consideration? If it is only nominal would that be consiedred a gift, or would it be considered a sale or a transfer of compensation?

The act of 1954, as interpreted by the General Counsel, which is an interpretation based on policy thinking rather than upon the law, I am confident, has been amended by this statute which the Senate ratified, which does authorize a gift if the President desires to.

Now, you testified that they will submit that to the Joint Committee and that is all that is required.

Senator PASTORE. That is right.

Mr. STRAUSS. There is a representative of the General Counsel's office here, who participated in the preparation of this opinion. Would you permit me to call on him?

Senator PASTORE. All right, Mr. Wells.

Mr. WELLS. Mr. Chairman, I think I can state the thinking that was behind the letter which has been referred to in response to Congressman Cole's question.

As to the explicit authorization that we referred to there we were thinking in terms of the specific act of Congress. In response to Senator Bricker's question, if I may, our opinion—that is the opinion of the General Counsel in formulating this letter—and my opinion today, is that the ratification of the statute itself does not increase the Commission's authority to donate material.

Now, it is clear that in an interpretation of this kind surely minds of reasonable men will differ.

Senator Pastore's interpretation differs from ours in that respect.

I can only say what we concluded using our best judgment in analyzing the statute as a whole.

Senator BRICKER. Are you talking of the statute of 1954?

Mr. WELLS. The statute of 1954.

To repeat it and summarize it, our view is that neither through the International Agency nor under bilateral agreement does the Commission have clear authority to make donation of substantial gifts of special nuclear materials, although we believe that it may legally make gifts of small research amounts to carry out the mandate of Congress to disseminate information.

Senator HICKENLOOPER. On what theory do you base that, that they can give small amounts?

For instance, I might envisage, if it were clearly set out, that there might be some mutual advantage flowing, such as the results of re-

search which would flow from that donation which might be considered adequate compensation if it were authorized, but I do not know if it is really authorized.

I mean there may be some considerations other than cash on the barrelhead that might be considered compensation and take it out of the gift category. But I do not know where that is found in the law.

Mr. WELLS. Mr. Hickenlooper, we came to this conclusion by reading all the provisions of the act and relying heavily on the general mandates of the Commission to encourage research on the peaceful use of atomic energy.

It is a construction, as I said earlier, before the Joint Committee, which we reached trying to put into effect what appeared to be the intent of Congress. I would certainly agree that there would be cases where you can get a quid pro quo by exchange of information with somebody and you might not consider the transfer a gift.

Senator HICKENLOOPER. By the same token, if there was a quid pro quo, it would seem to me it would have to be one which was identified and recognized as such. That is, I agree with some of the other statements that the reason why you can give fuel away, but you cannot give a suit away, is a little bit fuzzy in my mind.

Property is property whether it is ounces or tons.

As I said a moment ago, I can envisage the possibility of some quid pro quo other than cash in connection with research. But it would seem to me that would have to be pretty clearly defined and identified in connection with it to take it out of a gift category.

Now, let me ask you this: The authority to dispose of special material under a bilateral comes exclusively from the statute, does it not?

Mr. STRAUSS. That is right.

Senator HICKENLOOPER. Does the authority to dispose of fissionable materials under this statute come from the statute that is the international statute or does it come from the Atomic Energy Act?

Mr. WELLS. The only authority to dispose of special nuclear materials comes from the Atomic Energy Act of 1954.

Senator BRICKER. One minute at that point, if you will excuse me. The last word on this is article XIII:

"Reinbursement of members," and this is the supreme law of the land today under article VI of the Constitution:

> Unless otherwise agreed upon between the Board of Governors and the member furnishing the agency materials, services, equipment, or facilities, the board shall enter into an agreement with such member providing for reimbursement for the items furnished.

Now, that is the last law in regard to the furnishing of materials and it clearly implies there and says, "Unless otherwise agreed upon."

Now, that means that they can be contributed without compensation. If we are going to amend that we will have to do it by congressional action.

If we are going to require payment it will have to be written into this authorization statute, otherwise you can enter into an agreement for a gift.

Maybe Congress wants to, I do not know.

Mr. STRAUSS. Senator, I construe that quite differently. I construe that as a permissive arrangement that permits the agency to receive gifts, but is not an obligation on the part of members to contribute gifts.

Senator BRICKER. Not an obligation, but it is an authorization.

Mr. SMITH. May I draw your attention to article IX which controls article XIII, which limits our ability to make material available to the authority granted by the law of the United States and if the United States does not permit gifts, nothing in article XIII gives us any right to make gifts.

Senator BRICKER. But this is the law of the United States. The whole Agency statute, the International Agency statute, is the law of the United States. It becomes the supreme law under the Constitution.

Mr. SMITH. Article IXc adopts the Atomic Energy Act.

Senator BRICKER. It does not say that. You testified to that, it is true, I think that is the general understanding in the Senate on the ratification, but it is not clear by any means.

Mr. SMITH. May I read article IXc?

Senator BRICKER. Yes.

Mr. SMITH (reading)

ARTICLE IX. SUPPLYING OF MATERIALS

C. Each member shall notify the Agency of the quantities, form and composition of special fissionable materials, source materials and other materials which that member is prepared, in conformity with its laws, to make available immediately or during the period specified by our Board of Governors.

Senator BRICKER. What are our laws? That qualifies, amends, or restricts the law of 1954. This is the last word and the Agency statute becomes the supreme law of the land. It says "Unless otherwise agreed upon."

I do not think there is anything in the act of 1954 that prohibits a gift if the President sends the agreement to the Joint Committee. I think that is the only requirement that there is.

Senator PASTORE. Let me see if I can crystalize this argument.

Do you take the position that the section Senator Bricker just read is merely a section that means that if the United States Government desired to give this special nuclear material to the agency this is the section of the treaty that enables the agency to receive it, whereas subsection (c) of article IX is the one that empowers the United States to do thus and so?

Am I right in that interpretation?

Mr. STRAUSS. That is my interpretation.

Mr. WELLS. That is my interpretation.

Senator PASTORE. In other words, Mr. Bricker, the argument that is being made here, this article XIII that you are reading, is the one that gives the agency power to do a certain thing, whereas article IX is the section that affects the power of the United States to do certain things.

Senator BRICKER. I think that is rather involved legal reasoning, myself.

Have you any objection to writing it into the statute and clarifying what our rights are?

Mr. STRAUSS. Senator, I have a suggestion that might meet your point and go even beyond it as covering one which has been raised by you and Senator Hickenlooper on the subject of the small gifts of material or gifts of small amount of material for research purposes.

Senator BRICKER. I do not think any of us are concerned about that.

Mr. STRAUSS. I think it might be well to button that up. Here is the suggestion:

Suppose that the Atomic Energy Act itself were amended to provide that no gift in excess of some fixed dollar amount in value, small, $10,000 for instance, could be made in any 1 year by the commission to any 1 nation or cooperating group without the specific approval of the Congress. That would not only plug the loophole of gifts of gram amounts, for instrumentation and research purposes, but would also make it clear that in any subsequent year or at any other time where a large gift of fissionable material were contemplated for any reason whatever, political or otherwise, to the agency or to a nation or to a group of nations, the specific authorization of Congress would have to be obtained.

Senator BRICKER. That is what I was getting at in my reservation which now the court of appeals declared unconstitutional.

I would be willing to say that any contribution for medical research, for agricultural research, could be a gift as far as that is concerned. I have no hesitancy in going the full way on that.

Let the President contribute any amount that he wants to as long as it is for that purpose.

But when you come to the power program I think there ought to be some control in the hands of Congress over the amount of material that is disposed of.

Mr. STRAUSS. My suggestion was that there be an amendment to the Atomic Energy Act rather than to this participation statute and that it would then cover not only the Agency, but other activities of the Commission in connection with the bilateral agreement.

Senator BRICKER. Then you put the Congress in the position of having to seek two-thirds agreement on this bill which would become part of the fundamental law.

Senator HICKENLOOPER. You can amend the Atomic Energy Act. That is not inviolate. It is subject to amendment.

Senator BRICKER. You can amend the Participation Act.

Senator HICKENLOOPER. What I am trying to nail down here is the question which has been touched on as to whether or not this international statute from a legal standpoint gives any authority, irrespective of the laws of the United States, to dispose of any of the fissionable materials which we have.

Mr. STRAUSS. In contravention of the Atomic Energy Act? I am informed that it does not.

Senator HICKENLOOPER. In any event?

Mr. STRAUSS. I am informed that it does not.

Senator HICKENLOOPER. Then the next question is: Does any possible authority which the administration may have or acquire to donate, sell, or transfer fissionable materials to the International Agency, stem from statutory laws passed by the Congress, either past, present, or future, from a legal standpoint.

Mr. WELLS. If you would eliminate the word "give," the answer would be "Yes," and that it stems from the Atomic Energy Act.

Senator HICKENLOOPER. What do you mean "give"?

Mr. WELLS. Donate. I am referring to the previous discussion that we had that the authority to transfer materials stems from the Atomic Energy Act of 1954.

Senator HICKENLOOPER. Transfer can either be a gift, sale, or anything else.

Does that authority stem from statutory law passed by the Congress of the United States?

Mr. WELLS. Yes.

Senator HICKENLOOPER. Does this treaty in any way interfere with or change or alter that situation?

Mr. WELLS. It does not.

Senator HICKENLOOPER. So that this treaty does not create any authority on the part of the administration to divest the United States of ownership or property rights either for free or for compensation in special nuclear materials; is that correct?

Mr. WELLS. Except in accordance with section 124——

Senator HICKENLOOPER. Wait just a minute. I am talking about the statute in and of itself, standing alone. Let us forget about 124.

Mr. WELLS. In and of itself standing alone, it does not.

Senator HICKENLOOPER. So that under this treaty, any material of which the United States divests itself, that is in the performance of the terms of this treaty, that divestment must come as a result of authority under 124, 123, or any other provision of law which the Congress has passed which may be applicable.

Mr. WELLS. That is right.

Senator HICKENLOOPER. Then Congress, in spite of this treaty or under the treaty, or anything else, that is regardless of the existence of the treaty, in the implementation of this treay Congress has he power to regulate to the point of prohibition the disposal of fissionable material to the International Agency; is that correct?

Mr. STRAUSS. By gift?

Senator HICKENLOOPER. Any way, by gift, sale, Congress can say you have to sell them. Or Congress can say you can give 10 percent away, or Congress can say you can give a fraction of 1 percent away, or Congress can say you can only sell it for research purposes, or you can give it for research purposes, and so on, or that you cannot make any available for power purposes.

In other words, Congress retains the sovereign control over the disposition of this material, that is, the divesting of the United States of its property rights in this material.

Mr. STRAUSS. Through the provision, Senator, whereby those agreements that contemplate the sale or lease or divestment of this material are made and submitted to the Joint Committee for 30 days while Congress is in session before they became binding.

Senator HICKENLOOPER. I understand that, but I do not want us to get confused with the fact that there is anything sacred about section 123 or 124.

The same power that enacted 123 and 124 can alter it, repeal it, change it, amend it, or make different provisions.

Mr. STRAUSS. There is no contest on that.

Senator HICKENLOOPER. I agree that any contract we have already entered into validity we will keep. Those are contractual relationships entered into under authority of existing law. I am just leading up to the point that Congress has the power either in this act of participation, which is law, or will become law if it is passed and signed, or by amendment to the Atomic Energy Act, or any other law, has the power to write the terms and conditions if it sees fit.

I would like the legal opinion of counsel on this.

Mr. WELLS. Yes, sir; I agree with you.

Senator PASTORE. As Mr. Smith has brought out under article IX, subsection C, it says specifically:

"In conformity with its laws," and the basic law that we operate under is the atomic-energy law of 1954 and that is controlling.

Senator HICKENLOOPER. That does not limit it to the law in existence at the time of the adoption of the statute.

Senator PASTORE. As the law may be amended, or changed, later on in 1978.

Senator BRICKER. The law of the country has been amended if this statute is inconsistent with the act of 1954 or if it qualifies it in that way.

Now, I want to ask further if there is any objection to this amendment which I am going to submit:

> *Provided further*, That the United States shall not make special nuclear materials available to the International Atomic Energy Agency except to such an extent and in accordance with such provisions and conditions as may hereafter be authorized or prescribed by act or concurrent resolution of the Congress.

I would be willing to add further:

> except in the case of research material for medical purposes or agricultural purposes.

Mr. STRAUSS. Senator, may I ask for clarification. This is an amendment you would propose to offer to the atomic-energy law or to this Participation Act?

Senator BRICKER. To this act here.

Mr. STRAUSS. Would you mind reading it again?

Senator BRICKER. Will you read it. I have to vote.

Mr. NORRIS (reading):

> *Provided further*, That the United States shall not make special nuclear materials available to the International Atomic Energy Agency except to such extent and in accordance with such provisions and conditions as may hereafter be authorized or prescribed by act or concurrent resolution of the Congress.

Mr. STRAUSS. Of course, Mr. Chairman, I would like to think about that, and I suppose all of us would at some length, before commenting.

But this condition could arise that when the Agency meets, our British friends and our Russian associates in the Agency would be there with their contributions, we would not have anything. We would have to then wait for some specific authorization from the Congress.

It would not be a very enviable position to be in.

Representative COLE. Would you entertain the same objection if the suggestion of Mr. Bricker were to be modified in such a way as to permit the Commission to make transfer by way of sale without explicit authority from Congress which is in conformity, as I understand to be the interpretation by the Commission, of its authority under the present law?

Mr. STRAUSS. I think that would be acceptable, Mr. Cole.

Chairman DURHAM. Under this suggestion you would have to go to Congress for every sale you made, as I interpret it; is that correct?

Mr. NORRIS. Yes.

Chairman DURHAM. I believe that is what you said.

Mr. STRAUSS. I don't know what the force of it would be, for example, during the period when the Congress was not in session if it were necessary to make a sale. I would like to examine it and to give you a considered opinion.

Chairman DURHAM. We were discussing the suggestion made by Senator Bricker, Senator Hickenlooper.

Mr. STRAUSS. When Senator Bricker returns I would propose that the language include the right to sell and specifically exclude the necessity for coming to the Congress for authorization for the first 5,000 kilograms to which the President made mention last October, for the reason that otherwise we would be almost undoubtedly faced with the situation to which I referred a moment ago, that is to say, to find that the Agency would begin with the offers of amounts smaller than this perhaps on the part of two nations, members of the Agency, and nothing on the part of the United States which originated it.

Chairman DURHAM. You feel that that commitment has already been made?

Mr. STRAUSS. Yes, to the extent that the President was empowered to make it. He said that he would seek congressional authority upon the terms.

This was read into the record a short while ago by the chairman, being an excerpt from his message delivered to the delegates to the conference on the statute on October 23. He said:

Here is what I, on behalf of the United States, propose.

Then he said his first proposal would be when Congress reassembled he would submit the statute for ratification.

His second proposal was that the United States would make available to the agency on terms to be agreed the 5,000 kilograms. This he had in mind doing through the negotiation of the bilateral agreement with the Agency when it came into existence and the submission of that bilateral in the regular course to the joint committee.

Representative COLE. Did he have in mind that that would contemplate a gift of the material?

Mr. STRAUSS. He did not, and I so stated.

As a matter of fact, Mr. Cole, you are probably aware of the fact that there was strong advocacy at the time for a gift, and that a gift should be announced, and that consent of Congress should be sought to make a gift. This was resisted and the statement was made in this form indicating that there would be terms connected with this transfer and these terms would be specified on a later date.

Senator PASTORE. Would you gentlemen answer this question, any one of you:

If the Congress did decide to write into this implementation agreement or amend the law to the effect that Congress would have to initiate any legislation to transfer his material, what position would that put us in?

Mr. STRAUSS. Congress would have to initiate it.

Senator PASTORE. In other words, you could not give this without the consent of Congress and not by way of the bilaterals that we have been talking about, which is a consummated agreement after it lies here for 30 days.

What position would we be placed in?

I think the record ought to show the position of the President and the State Department quite clearly on this subject.

Mr. STRAUSS. May I ask you for a clarification? Now, you are speaking of gift?

Senator PASTORE. I am speaking of anything. Even the transfer of material.

In other words, you would have to come here like you come here for foreign aid grants or mutual assistance grants, or any appropriation to your department before you could have any money.

Before this agency could have any material from the United States under any terms, under any conditions, either by gift or by payment, Congress would have to authorize it and grant it.

Now, what position would that put us in? Do you think that is a fair question, Mr. Bricker?

Senator BRICKER. Certainly.

Senator PASTORE. I think the record ought to show that because I think there are some people who feel that way and I think we ought to clear the record.

Mr. STRAUSS. I think, Mr. Chairman, that this would effectively take over an administrative function of the Commission which is presently safeguarded by the device originating with the Congress of having no transfer of substantial amounts of fissionable material occur except by specific provision of an instrument that has to be approved by the President of the United States as contributing to the common defense and security and the best interest of the Government of the United States. When that assurance from the President reaches the Joint Committee as the representative of the Congress during the session of Congress and remains before the Joint Committee for a period of 30 days before it becomes binding.

It seems to me that that is not only an adequate safeguard, but has been successfully operating now for better than 2 years without any incident having arisen to bring it into question so far as I am aware.

Representative COLE. Mr. Chairman, it seems to me that the problem that is disturbing to us is the authority of the Commission on behalf of the Government to give the material away.

If the Commission will commit itself to distributing material abroad by way of bilateral agreement only in those cases where the Commission makes the full charge for the material, I can see no criticism of that process.

However, if the Commission decides that it is justified in making a gift of the material abroad, then I think very definitely the authority should be obtained from Congress before it does it.

Mr. STRAUSS. There is no disagreement on that, Mr. Cole.

Senator PASTORE. I want to clear the record on another point, Mr. Cole. It is my function to clear this record up because questions will come up and I think, myself, these representatives, representing these very important departments who have very intimate contact with this legislation and with these negotiations ought to state their views on the record.

I think we ought to have it on the record. Mr. Wilcox and Mr. Smith, would you care to comment on the question I raised?

What would it do to us, how would it embarrass us, how would it tie our hands, what would be the advantages or disadvantages in carrying out the suggestion I just made?

Mr. SMITH. In the first instance, Mr. Chairman, I would like to go back to Mr. Strauss' point about what happens 3 months after the entry into force of this treaty.

Under article IX–F the countries that are proposing to supply this agency have to make an initial notification as to how much they are willing to sell.

The Soviet Union under present conditions could say "We will offer to sell 50 times more than the United States." If they put up 50 kilograms or infinitesimal times more because we would come up with a goose egg.

We would say, "I am sorry; Congress will assemble in January and perhaps we will get some authorization, we don't know."

That will have a tremendous impact on our ability to get our way in this agency.

That is one important practical consideration. If we divorce ourselves from any ability to transfer material from this agency until an uncertain contingency next year——

Senator BRICKER. That is true now under section 124.

Mr. SMITH. Of which act?

Senator BRICKER. Of the act of 1954. You have to file it with the Joint Committee. It cannot become effective until Congress comes back anyway.

Mr. SMITH. We hope that when the machinery is established we will not have to try to operate under conditions of uncertainty.

Senator BRICKER. Is there any more uncertaintly in this than there would be in the present law?

Mr. SMITH. We have authority now, we believe. If during this 30-day period the Congress amended the Atomic Energy Act or repealed section 124, granted that authority would be taken away, but I think one is in a better condition if one has authority and a condition subsequent on it than if one has no authority at all and has to seek it next year.

Representative PRICE. Under the practical application of section 124, you can make an actual proposal and you submit it to Congress and it lies there. Even if Congress did object to it, you could enforce that proposal. You do have some authority under section 124 to make an actual proposal which you would not have if you were not operating under 124.

Senator PASTORE. In other words, the difference here is that in one instance under the present law you would have the authority to enter into an agreement. The other way you would not have authority to enter into an agreement.

You would have to wait for Congress to make the agreement.

Senator BRICKER. Congress could either authorize the agreement in advance or if submitted it would act just exactly as the committee acts now, it could pass upon it when it comes down here, the same way as we make appropriations of money.

The Congress is the authority of the Government which is entitled under the Constitution to dispossess this country of any of its material or property.

Now, we are transferring it in effect to the President. That is the only thought that I have in mind.

Article 124 of the Atomic Energy Act is in fact a transfer of authority to the President to dispossess the property of this country. If

Congress passes an act, if they were dissatisfied with the amount of money that was paid for the material or the amount of material that was contributed, the President could veto it, and it takes two-thirds to overcome it which you cannot get. You know that as well as I do.

The practical effect is that we are transferring the constitutional authority of Congress to dispossess this country of material or property to the President of the United States.

Senatore Pastore. Mr. Strauss, could the Commission today enter into an agreement with the Yankee Atomic Energy Co. to sell it 5,000 kilograms of U-235 without coming to Congress?

Mr. Strauss. Yes. You could lease it.

Senator Bricker. You have to lease it to them?

Senator Pastore. Could you enter in an agreement to lease it?

Mr. Strauss. Without coming to Congress?

Sentor Bracker. Yes.

Mr. Strauss. We could; yes.

Senator Pastore. In so far as these two situations are concerned, would you say they are analogous?

Mr. Strauss. No, I don't think they are quite analogous, Senator, because we do not have to have a bilateral agreement with an American purchaser.

There are certain things that have to be done in the case of the American purchaser. He has to be licensed to use and to operate, but in the case of the foreign purchase, there has to be a bilateral agreement and that bilateral agreement has to specify the use that is to be put to the material and what is a happen to the material during the period that it cannot be used for other than peaceful purposes.

Senator Pastore. But if the argument were made that maybe we do not have enough U-235 to dispose of it even at a price—let us assume that argument was made—is it not a fact you have that authority without coming to the Congress to dispose of U-235 and transfer it to domestic users without having to initiate it in the Congress first?

Mr. Strauss. You asked the question, and I was, therefore, answering your question from the position of nuclear plenty. You changed it. You said assuming we didn't have this amount available.

Senator Pastore. I said if the argument was made that the reason why they want you to come to Congress is because they want Congress to determine what stockpile we have and whether or not we have any to make available either domesticwise or foreignwise, even at a price, and we were talking about the authority of the Commission to act without direct authorization from Congress.

The fact of the matter is that under our present law today the Atomic Energy Commission has the authority to lease to domestic users, U-235 without direct authority from Congress as to the amount which will go to X company.

Mr. Strauss. That is true.

But, Senator, you have overlooked the fact that because of the close relationship in the Commission and the Joint Committee, such negotiations would be known to the Joint Committee over a period of time and it would be impossible for such a thing to come to you as a surprise.

With you permission, I would like to return to a suggestion I have made which I think meets all the points that have been raised here;

namely, that material should not be contributed or given away without the express prior approval or authorization of the Congress and that small amounts should not be indiscriminately given.

I would suggest, Mr. Chairman and gentlemen, that if your staff and the staff of the Commission were delegated the responsibility of preparing or drafting an amendment to the Atomic Energy Act rather than to this participation act, which would then cover not only the Agency but all other parties, nations, or groups of nations, with which the Commission might deal, we could provide that there would be no gift in any year to any nation or any group of nations or any agency in excess of some small fixed dollar amount by the Commission without congressional authorization in advance.

Now, that would clearly cover any large contribution. It would make any large contribution impossible without prior congressional authorization.

Senator PASTORE. You mean gratis contribution?

Mr. STRAUSS. I used the word "contribution" as a transfer without compensation.

Senator BRICKER. Why would you rather have that in the Atomic Energy Act?

Mr. STRAUSS. For the reason, Senator Bricker, under those circumstances it would cover Euratom; it would cover the various other countries with which we have bilateral agreements and which will be amended, let us say, in the future.

Whereas if it is in the statute, the participation act, it would refer, I presume, only to the relationship between the Atomic Energy Commission and the International Agency.

Senator BRICKER. We could amend the Atomic Energy Act in this participation act if we wanted to. It is not a question of whether or not we want to or whether it is desirable to do it as you suggest, or in this way.

What is your thinking on that?

Mr. STRAUSS. I have no preference as to that. I thought it was a cleaner method to keep amendments to the Atomic Energy Act within that pice of organic legislation rather than spread out.

Representative COLE. That brings up a thought which I hope to explore with the representatives of the executive department: That is, that the participation act be written in such fashion that it is an amendment to the basic atomic-energy law, because the participation act is contemplated to be a permanent law in the atomic-energy field.

It would be my hope that any legislation of a permanent nature affecting atomic energy will be by way of amendment to the basic atomic-energy law so that in the future anybody who seeks a question pertaining to atomic energy can get the one law and all phases of atomic energy will be written into that.

Senator HICKENLOOPER. I wonder what effect it would have if some amendments were adopted to the statute which we did not approve and we retired from the Agency.

Representative COLE. Instead of repealing the Participation Act as an entity, you would simply adopt an amendment repealing certain sections of the Atomic Energy Act.

Senator HICKENLOOPER. I was thinking about the cleanness of the legislation.

Representative COLE. Do you gentlemen have any comment to make on that?

Mr. STRAUSS. Secretary Wilcox does have comment on that point.

Mr. WILCOX. While I have not had a chance to consult with my colleagues in the State Department, I would prefer that the Participation Act be a separate piece of legislation. It seems to me if it were attached to the Atomic Energy Act it would in itself confer primary responsibility for the agency upon the Atomic Energy Commission.

We have very carefully worked in harmony with the Atomic Energy Commission. We hope to keep our relations very close, but I think that any consolidation of the Participation Act and the Atomic Energy Act which would in itself constitute a conferring of primary responsibility for the Agency upon the Commission might do damage to this close working relationship that we have developed over the last 6 or 8 or 10 months.

Representative COLE. That conferring of responsibility would be only by way of inference; it would not need to be explicit in the amendment to the basic law.

Mr. WILCOX. Perhaps so.

Senator BRICKER. Under the Participation Act, who would file the articles of cooperation or the cooperation agreements with the Joint Committee? Would the State Department do that, or would the Atomic Energy Commission do it?

Mr. WILCOX. It is my understanding it is the Atomic Energy Commission. We would not want to disturb that relationship.

Senator BRICKER. The suggestion of Congressman Cole would not disturb that relationship. It would leave it right where it is.

Mr. WILCOX. That is correct.

Senator PASTORE. Will you give us some thought and let us know how you feel about that?

But I would like to have Mr. Smith conclude the statement he was making with reference to the political aspect of the question that I raised because I think it is quite important to have it in the record. I would like to have Mr. Smith conclude the statement he started to make.

Mr. SMITH. There is one other point I think we will have to look out for. That is that the Soviets in the last year or two have made quite a point about an apparent American willingness to make offers specifically in the disarmament field. Mind you, this was a propaganda line.

As soon as other countries have a disposition to accept their offers, the United States, according to the Soviets, pulls back—welshes, in effect.

Now, I think they would be given a marvelous propaganda opportunity here if, after the President made this proposal in 1953, and the Congress of the United States in 1954 specifically offered an avenue for us to proceed under in sections 124 and 123, and we proceeded under it in reliance on that authority to negotiate the statute, and we got a lot of countries to agree to a very unpleasant system of safeguards—some 80 countries have signed this statute; we think a great many will ratify it—after having gone down that avenue, if the United States then withdraws the authority which the executive branch has to support this Agency, I think we will be wide open to

that claim that we have made a proposition and now we are pulling back from it.

I think that will have intense political repercussions.

Senator PASTORE. I am happy to have that in the record.

Mr. WADSWORTH. Could I add one more thing on this basis of the original suggestion by Senator Bricker, without any of the possible amendments? In the event that this were attached to the Participation Act and in the event that the act were passed and signed by the President, this could have only two effects, as I see it, on the International Agency.

The one has already been referred to by Mr. Smith, which is the question of our going emptyhanded to the General Conference and the loss of influence and prestige as far as the Agency is concerned.

The second is a far more practical and not as political a consideration. Let us assume that if we go emptyhanded to the Agency, that the only other countries capable of giving any amount of fissionable material do not put up a great deal; this will mean that the Agency in reality will not operate.

Any country that wishes to get up a project to receive Agency assistance must go through a tremendous expense and a great deal of trouble working out the project with the Agency; then the Board of Governors has to examine it in accordance with all those criteria that we mentioned, and there is a tremendous amount of difficulty which will be experienced, particularly by the applicant country.

It stands to reason that if there is no certainty that an applicant country will receive any material, will receive any of this assistance, it will not even bother to make application.

For if they look many months ahead and see at the end of this particular road on which we are traveling that there must be a specific authorization by the Congress of the United States which cannot be guaranteed at all, which cannot even be held forth, they won't apply. Then there won't be any use for an Agency.

That is an oversimplification, of course, but I feel it is something that should be thought about.

Senator BRICKER. In other words, you do not trust that the Congress will pass any acts that will be reasonable?

Mr. WADSWORTH. That is not the point. The point is timewise for one thing.

Senator BRICKER. How soon do you expect to put this in operation? How soon do you expect us to deliver this material?

Mr. WADSWORTH. The Congress may not be in session at the time the project is completed.

Senator BRICKER. Will you please answer my question: When do you anticipate you will be delivering this material?

Mr. STRAUSS. May I answer that?

Senator BRICKER. Yes.

Mr. STRAUSS. It may be some years before material is delivered.

Senator BRICKER. Some years?

Mr. STRAUSS. Yes, but the project will have to be approved much earlier.

Senator BRICKER. So the argument of the Ambassador will be completely false. Congress will have plenty of time to act before you will be able to deliver any material. We can look at it and we can determine what terms it will be sold on, and how much.

Mr. WADSWORTH. I construed your amendment as requiring that when the United States receives a request for materials for a project, that then the Executive comes to the Congress.

Senator BRICKER. I anticipate there will be a general statute on it. I do not think there is any question about it.

Mr. WADSWORTH. It would be in advance then.

Senator BRICKER. Certainly. It could be just as well as afterward.

Mr. WADSWORTH. That is not the way I read your amendment.

Senator BRICKER. It would not change the Constitution or the power of the Congress to act.

Mr. WADSWORTH. I still believe if it should go to the point I described, and I am glad to be corrected on that, then indeed it would be catastrophic to the Agency. If that is not the case, then my argument does lose a good deal of validity.

But that still does not mean that we believe that this thing should go on this particular piece of legislation. I would like to just deal with that for a moment.

Mr. Chairman, the entire text of the Participation Act is as you see a simple formula for setting up representation to the Agency. In my opinion an amendment to this, having to do with transfer of materials, would be slightly incongruous.

I don't think it would be illegal. It would be something that would stick out like a sore thumb.

Senator PASTORE. And raise suspicion.

Mr. WADSWORTH. And raise suspicion, also. So I believe that an amendment of the type suggested by Chairman Strauss, if the Congress wished to make more limitation on the way in which materials can be transferred abroad, would be far more proper.

I believe, in common with Congressman Cole, if we got to a position where we felt we could no longer remain in the Agency we would repeal the Participation Act and go through the other things that have already been set forth in the understanding of Senators Knowland and Hickenlooper and the Executive pulls you out of the organization.

Chairman DURHAM. We have handled all the military application of weapons and everything through the AEC. All that legislation comes through AEC amendments.

Mr. WADSWORTH. Transfer of materials of course always will come through the AEC. This Participation Act is merely to allow the United States to send representatives to the IAEA, and it talks about their pay and travel allowances and things of that sort.

I don't believe this amendment would be particularly proper for that kind of legislation.

Senator PASTORE. On this subject of incongruity that was raised by Ambassador Wadsworth, with reference to putting some limitation as to a gift or contribution, would you want to see that in the basic law of 1954, or would you write it in the implementation legislation?

Mr. STRAUSS. My preference would be to see it in the basic law, but it is not a strong feeling. I don't believe that counsel see any difference in it.

I am impressed by Secretary Wilcox's point that the Participation Act should stand alone, since it seems to involve in his mind, and may very well in the minds of others, some unspecified shift of authority or responsibility from State to Atomic Energy Commission for a foreign relations aspect.

Certainly that was not intended. We do have some parental feeling of responsibility for this Agency which is understandable, but we would not expect, and are not staffed or equipped, to operate another small State Department in the Atomic Energy Commission.

And we have very close and satisfactory working arrangements with the Department of State. I do not suppose that any two organizations in the Government have ever been in such continuous daily contact as we are.

If the amendment which I have suggested should meet with the favor of the Joint Committee, I think the proper place for it would be in the Atomic Energy Act since it in effect qualifies sections 123 and 124 and could refer to them specifically.

Chairman Durham. At the present time you are already dealing with the State Department on agreements. This is nothing more than an added number of agreements. That is what it amounts to.

Representative Cole. I fail to see where there is any greater responsibility on the State Department with respect to the International Agency than presently exists with respect to bilateral agreements or is anticipated will exist with respect to the Euratom agreement.

Mr. Smith. If I may speak to that, Mr. Cole, the relationship between the United States and this Agency will not only be a matter of making agreements; it will be a matter of continuous day-to-day and week-to-week and month-to-month policymaking, and I think we should not think of this as just an extension of agreements for cooperation.

We are going to be working to set up health and safety codes, security systems. Now, in all of these things there are large political implications.

Representative Cole. Could your objection not be readily resolved by providing in the language in the participation act, even though it is by way of amendment to the basic atomic-energy law, that this shall be under the direction of the Secretary of State?

Mr. Smith. I think that basically it is a matter of legislative artistry on which I would be happy to bow to you, but my feeling is that it would be as inartistic to provide for United States participation in this Agency by amending the Atomic Energy Act as it would be to provide for United States participation in the United States International Labor Organization by amendment to the Wagner Act.

Representative Cole. Those are not comparable at all.

Mr. Smith. I think this is a question of setting up the relationship between the United States and International Agency which deserves separate treatment.

Representative Cole. It is not comparable at all. The Wagner law is domestic law. The Atomic Energy Act is both international and domestic.

Representative Price. It started as domestic law.

Representative Cole. As of now it covers the field of atomic energy both at home and abroad.

Mr. Strauss. I think the place where this should be enacted, if indeed it is enacted, is of relatively less concern to the executive branch than it is to you gentlemen.

Senator Pastore. Mr. Strauss, may I suggest, then, that you have your legal department forward an amendment to carry out the suggestion that you have made?

Mr. STRAUSS. I would like to cooperate on that with counsel for the Department of State and submit it in very short order.

Senator BRICKER. You see the situation here we are in now. I proposed this as a reservation—whether binding or not is to be determined by what the Supreme Court says on the Niagara Power Treaty—to the treaty, feeling that it was simply preserving the constitutional relationship of the President and the Congress which I thought ought to be done.

I was told then by the leadership and by those on the other side that it ought to be a part of the participation act.

Now we come to the participation act and then we are told it ought to be a part of the Atomic Energy Act. I am finally going to run this thing down in a hole somewhere because I think it is sound law.

I think it is in conformity with the constitutional principles.

Mr. STRAUSS. I will buy it either way.

Representative COLE. I wonder if I may be permitted to go into another subject.

Senator PASTORE. Yes.

Representative COLE. I would like to have the observation of the witnesses with respect to a thought that has occurred to me. This International Agency, as I see it, is not of the general type of a special agency of the United Nations. It is for a specific purpose which is highly technical, specialized in its field.

Since most of the program has been under Government sponsorship and, therefore, most of these technicians are Government employees, it occurs to me that a great many of them, if at all, would be very loathe to leave their Federal connection and thereby sacrifice their retirement rights, whatever Federal emoluments they may have as a Federal employee, in order to go over to this Federal Agency.

I would like to inquire of you, any of you who wishes to respond, whether that objective has any merit, trying to revise our laws in such fashion as may be necessary to make it attractive to Federal employees in the atomic program to move over into the international program.

Mr. WILCOX. Would you want to limit that, Congressman Cole, to employees in the Atomic Energy program? It is conceivable that Foreign Service officers or officers from some other department and under civil service might want to transfer for one reason or another to the Atomic Energy Agency for a period of service.

We think this is a very laudable objective. In fact, the Department has been trying to do its best for some time to encourage qualified Americans to take responsible positions in other international organizations in which we participate. We think it is highly important that this objective be worked upon in connection with the Atomic Energy Agency.

Representative COLE. Have you found that these employees who would like to move into the international field are hesitant or refuse to make the transfer for that reason?

Mr. WILCOX. They are hesitant for 2 or 3 reasons. One is the objectionable features perhaps of uprooting themselves and their homes and moving abroad for a period of time. That is something we can all appreciate.

The second one is the salary factor. The wages and salaries of the United States are quite high and it is very difficult to attract able

people from responsible position in the United States to go abroad for a period of years and to take perhaps a reduction in salary.

The third factor is that those individuals who are working for the Federal Government find that the way is not entirely clear for them to take leave of absence for a period of 2 or 3 years because they do not retain their full retirement rights and retain other benefits which normally accrue to them under civil service.

I, therefore, feel that your suggestion in the direction of paving the way to attract competent people to accept positions in this Agency is a very laudable one and that we ought to do what we can to facilitate it.

Representative COLE. I did not have in mind limiting it to just atomic-energy scientists, but any Federal employee, of the Justice Department, or any Federal activity.

Chairman DURHAM. Do they not retain their rights now when they go to the United Nations?

Mr. WILCOX. Not all of their rights, sir. The provisions in our Federal employment setup to protect an employee's benefits are not sufficiently broad to encourage Federal personnel to take leave of absence to go into the United Nations to make a contribution there.

Now we are working on that and hope that the way will soon be paved for any employee of the civil service to make such contributions.

Chairman DURHAM. You mean if you take somebody out of the State Department at the present time and transfer them up to the United Nations to do a job, they lose all their civil-service retirement?

Mr. WILCOX. Well, sir, we have not done that——

Senator PASTORE. You do not mean to the United States mission to the United Nations. You mean to work under the direction of the Secretary General of the United Nations?

Chairman DURHAM. Yes.

Mr. WILCOX. There are two things involved. Our mission in New York under Ambassador Lodge and Ambassador Wadsworth does, of course, employ a good many people that are under civil service and there are some Foreign Service officers there.

But with reference to the secretariat of an international organization, we do not have a completely satisfactory method of placing on leave for a limited period of time Federal personnel who can make contributions to such an organization.

So we are working on that.

Senator HICKENLOOPER. Does the United Nations have a system of retirement, and so on, of its own?

Mr. WILCOX. It does; yes.

If a person wants to resign from the Federal service to go to the United Nations, of course, that is his option. He may do so, but I think what Congressman Cole is suggesting goes somewhat beyond that. It opens the way to a loan for a period of time, 2 or 3 years perhaps, of qualified people for special services.

I think, myself, it would be very helpful to us in our relations with this Agency and in our relations with other international organizations, in which we might participate.

Representative COLE. This is a subject which perhaps can be explored more fully in the executive session so I do not care to prolong the discussion today, but I would urge that Mr. Wilcox and the others

give some further thought and submit language which will accomplish what we have in mind.

Of course, that will not apply to the persons covered by the participation act.

Mr. WILCOX. No, that is correct.

Senator PASTORE. In other words, this subject you have raised, you have no intention of having it included in this?

Representative COLE. Yes.

Senator PASTORE. Then will you submit a statement with reference to that?

Mr. WILCOX. We will be glad to do it.

Senator PASTORE. So that we can study it in executive session.

Is that agreeable to you, Mr. Cole?

Representative COLE. Yes.

Senator PASTORE. Are there any further questions?

Is there any further statement desired to be made by any of the witnesses here?

Are there any other witnesses who desire to speak on this subject?

This is a public hearing. The Chair hearing none, the hearings will come to a close under the conditions we have made about the suggested amendment and the statement with reference to the civil service and retirement status.

Mr. STRAUSS. I would like to express our appreciation for the opportunity of appearing.

Senator PASTORE. It is a pleasure and joy to have you gentlemen.

(Thereupon, at 12:25 the Joint Committee hearing was concluded.)

REVIEW OF PROPOSALS UNDER POWER DEMONSTRATION PROGRAM

TUESDAY, SEPTEMBER 17, 1957

CONGRESS OF THE UNITED STATES,
SUBCOMMITTEE ON LEGISLATION OF THE
JOINT COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The subcommittee met at 1:30 p. m., pursuant to notice, in the Old Supreme Court Chamber of the Capitol, Representative Chet Holifield (chairman of the subcommittee) presiding.

Present: Representatives Durham (chairman of the full committee) and Holifield (presiding).

Present also: James T. Ramey, executive director of the Joint Committee, George Norris, Jr., committee counsel, John T. Conway and David R. Toll, professional staff members.

Representative HOLIFIELD. The hearing will be in order.

This is a hearing before the Subcommittee on Authorization Legislation, and the purpose of this hearing today is to hear an explanation of the basis of proposals under the power demonstration program negotiated by AEC with three utilities which have been submitted by the Commission for review by the Joint Committee by letters dated September 13 and September 16. The three proposed arrangements are with the following organizations: Consumers Public Power of Columbus, Nebr., Northern States Power Co., of Minnesota, and Rural Cooperative Association of Elk River, Minn.

It is the committee's intent as set forth in the legislative history of section 111 b. of the Authorization Act to consider the bases of these proposed arrangements with a view to determining whether the committee will waive the requirements that such arrangements be submitted while Congress is in session and to also waive the 45-day waiting period.

(The text of a resolution approved by the Joint Committee on September 19, 1957, waiving the 45-day requirement for the Consumers and Northern States proposals will be found on p. 63.)

Representative HOLIFIELD. We would like to have a status report today on the other outstanding co-op arrangements if the Commission is ready to give it.

The second purpose of the hearing is to obtain a status report from the Commission on other items in the Authorization Act in which the Joint Committee is particularly interested. This would include the gas-cooled reactor development and design study and the plutonium design study as well as the plutonium recycle reactor.

At this point I would like to put into the record a letter from Chairman Durham dated August 24, 1957, which explains the background

of this hearing. Also I would like to put into the record the Commission's letters of September 13 and 16, together with the backup information on the three cooperative agreements. Further, without objection, I would also put in the committee's letter to the AEC announcing today's hearing together with the press release on it, dated September 14 and 16, respectively.

(The documents referred to follow:)

CONGRESS OF THE UNITED STATES,
JOINT COMMITTEE ON ATOMIC ENERGY,
August 24, 1957.

Hon. LEWIS L. STRAUSS,
Chairman, Atomic Energy Commission,
Washington, D. C.

DEAR MR. CHAIRMAN: As you know, the AEC authorization bill has become law and the Congress has completed the processes of appropriating funds for the AEC thereunder.

I am sure you recognize that the members of the Joint Committee took an active part on the floor and in the House and Senate Appropriations Committees in obtaining and restoring necessary AEC funds.

In the Joint Committee's report on the authorization bill and during the floor debate on the authorization bill, as well as the hearings and debate on the appropriation measure, it was made clear that the Joint Committee would do everything practicable to expedite consideration of the basis of arrangements under section 111b, when they are submitted for committee review by the AEC. In particular I believe it is the committee's intent to expedite review of those arrangements which were in the final stage of consideration by the AEC at the time of the authorization hearing. It was our understanding that the Elk River project and possibly the Consumers Public Power project of Nebraska were in this category. We also understand that the Northern States arrangement may also be ready.

I am making arrangements with Congressman Melvin Price, chairman of the Research and Development Subcommittee, for members of his subcommittee to review the basis of any arrangement submitted to the Joint Committee during the recess.

As you know, a number of the committee members are going abroad on official business to the Vienna Conference, departing September 20. In order therefore for the subcommittee to review the basis of any arrangements and for the staff to obtain the necessary waiver, it would appear advisable for the Commission to submit any such basis on or before September 13, at the committee offices. After a brief staff review, Mr. Price may decide to hold a short hearing on the project in which AEC, the utility organization, and the equipment manufacturers would be requested to appear. Following the hearing, if the project appeared to represent no substantial problems, I would plan to poll all members to waive the remainder of the 45-day period.

The Joint Committee after the Vienna trip would also be in a position to review the basis of additional arrangements beginning around October 20.

With respect to the projects in which the Joint Committee was especially interested in the authorization bill it is of course expected that the Commission will proceed with these projects in good faith in accordance with the intent of the committee and the Congress. This would include project 58-b-8, plutonium production reactor design; project 58-e-14, natural uranium, graphite moderated, gas cooled power reactor prototype design; project 58-e-15, plutonium recycle experimental reactor; section 107b (2), Brookhaven cosmotron project; and section 111a (1), (2), and (3).

Sincerely yours,

CARL T. DURHAM, *Chairman.*

ATOMIC ENERGY COMMISSION,
Washington, D. C., September 13, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: In accordance with the provisions of section 111 (b) of Public Law 85–162, I am transmitting herewith for your approval the basis of the arrangements which the Commission proposes to enter into covering power reactor demonstration projects with the following organizations:

1. Consumers Public Power District of Columbus, Nebr.
2. Northern States Power Co., Minneapolis, Minn.

In connection with these projects, we have requested the views of the Comptroller General as to the authority of the Commission to enter into present contractual undertakings to make payments during the period of operation. We anticipate a reply in the very near future and will advise you as soon as it has been received.

Your letter to me of August 24, 1957, indicated that, if submitted to you by September 13, 1957, these arrangements would receive your early consideration. We appreciate the cooperation you are extending in this matter.

Proposed arrangements with Rural Cooperative Power Association, Elk River, Minn., are not being submitted, since agreement has not been reached, but negotiations are still in progress and we hope to be able to make a separate submission to you before the hearings take place.

Your letter of August 24 also expressed interest in our plans for other projects which were included in the fiscal year 1958 Authorization Act. I am, therefore, including in this letter a brief report on these projects:

(*a*) Project 58–e–14, natural uranium graphite moderated, gas cooled, power reactor prototype; development, design, and engineering only; report on design required by April 1, 1958: An invitation was issued on August 29, 1957, for architect-engineers to submit proposals to develop design criteria and prepare an engineering design and cost estimate of a gas-cooled civilian power reactor of 40,000 kilowatts (electrical). It is expected that a selection of the contractor will be made by mid-October.

(*b*) Project 58–e–15, plutonium recycle experimental reactor designed for the production of 15,000 electrical kilowatt equivalent: Design work previously initiated at Hanford is continuing on an accelerated basis. Current planning includes the placing of procurement contracts for long lead delivery time items in October–November 1957 with ground breaking and construction estimated to begin about January 1958. Construction time is tentatively estimated at 18 to 24 months.

(*c*) Project 58–b–8, production reactor for special nuclear materials; development, design, and engineering only; report on design required by April 1, 1958: Our plans regarding this project were reported to you in our letter dated September 4, 1957, from Mr. R. W. Cook, Acting General Manager.

(*d*) Project 57–h–5, cosmotron target area, Brookhaven National Laboratory: Major procurement action and the award of a contract for architect-engineering work are scheduled for October 1957, the project to include the second phase of modifications contemplated by the authorization of $3,550,000. Award of a contract for the construction of the building and installation of necessary equipment is scheduled for May 1958.

Sincerely yours,

H. S. VANCE, *Chairman.*

ATOMIC ENERGY COMMISSION PROGRAM JUSTIFICATION DATA FOR COOPERATIVE ARRANGEMENTS

Submitted to the Joint Committee on Atomic Energy pursuant to section 111 (b) of Public Law 162, 85th Congress, September 13, 1957, 58–111–1 Consumers Public Power District of Nebraska; 58–111–2 Northern States Power Co., Minneapolis, Minn.

ARRANGEMENT NO. 58–111–1

A. Name of contractors

1. Atomics International Division, North American Aviation Co., for research, development, and nuclear design.
2. Architect engineer and construction contractors to be selected.
3. Consumers Public Power District of Nebraska for operation of reactor.

B. Description of proposed project

1. Objective: The objective of the proposed contract with the Consumers Public Power District of Nebraska is to encourage and accelerate effective development of nuclear power technology and the achievement of commercially feasible nuclear power. A sodium-cooled, graphite-moderated reactor designed to produce 710,000 pounds of steam per hour and 75,000 net electric kilowatts of energy, will be constructed by the Commission. Consumers will provide the site and turbogenerating facilities and will operate the entire plant for 5 years. It is the intent of the parties that the plant will be operated for the primary purpose of producing the maximum amount of electric energy therefrom.

2. Location: Near Hallam, Lancaster County, Nebr.

3. Technical aspects (data are approximate):

Heat output: 245 megawatts.
Electrical output (net): 75 megawatts.
Amount of fuel loading: 23,800 kilograms.
Enrichment percent U-235: 2.5 percent.
Moderator: graphite.
Coolant: sodium.
Reactor outlet temperature: 925° F.
Reactor pressure: 50 pounds per square inch.
Steam conditions: 800 pounds per square inch gage at 825° F.
Byproduct utilization to be investigated by consumers.

4. Estimated date of completion of reactor: Mid-1961.

C. Estimates of cost

[In thousands]

Element of cost	Allocation of estimated costs		
	Total	AEC	Consumers
1. Preconstruction research and development	$18,165	$18,165	
2. Plant construction:			
(a) Reactor	29,233	24,013	[1] $5,220
(b) Turbo generating facilities	11,350		11,350
Subtotal construction	40,583	24,013	16,570
3. Postconstruction assistance		[2] 8,000	
4. Waiver of fuel use charges		1,325	
5. Total value of AEC assistance		51,503	

[1] Fixed amount, subject to escalation within 25 percent.
[2] Fuel and extraordinary maintenance costs.

D. General features of proposed arrangements

1. Architect-engineer and construction contractors (to be selected). It is expected that the Commission will enter into prime contracts with the architect-engineer and construction contractors under arrangements to be established.

2. Consumers Public Power District—

(*a*) *Site.*—Under the contract, Consumers will furnish the site for the plant, comprising approximately 600 acres and located near Hallam, Nebr. Title and control of the site will rest with Consumers. The area upon which the reactor portion of the plant will be located will be made available to the Commission by a 40-year rent-free lease.

(*b*) *Construction.*—Consumers will furnish the turbine generator facilities without cost to the Commission. Consumers will also furnish materials, equipment, facilities, and services for construction of the nuclear portion of the plant at a cost of $5,220,000. Insofar as is feasible, title to the facilities so furnished by Consumers will be retained by Consumers. The dollar amount of this assistance will be subject to escalation with a limit of 25 percent above or below the figure indicated.

The Commission will furnish the reactor facilities, except as noted above.

(*c*) *Operations.*—Consumers will utilize all the steam produced by the reactor for the generation of electricity and will operate and maintain both the turbogenerator and reactor facilities. Except for the first fuel loading Consumers will pay for fuel cycle costs up to an amount per kilogram of uranium metal

which has been tentatively fixed at $36.40, such amount being subject to upward and downward escalation based on the average cost of fossil fuels.

The Commission will pay for extraordinary repairs and maintenance required in operation of the reactor facilities. AEC will furnish the initial fuel loading and pay for subsequent fuel cycle costs in excess of the amount contemplated per kilogram of uranium metal incorporated into the fuel. There will be no credits to Consumers for plutonium recovered.

Consumers is assuming certain basic risks in the project, including the possibility that the fuel life will be less than the 3,000-megawatt days per ton objective, and the risk that operations, including ordinary maintenance and repairs, will be in excess of the amount estimated. Consumers therefore has every incentive to keep nuclear power costs to the minimum. However, in the event that Consumers is able to pay more for fuel than the amount presently contemplated because the cost of power generated in the nuclear plant falls below that of power conventionally generated, negotiations will be held to reduce the Commission's assistance on fuel costs.

(*d*) *Term.*—The contract will be effective upon execution and will continue for a period of 5 years after the nuclear facilities become operable as a power producer, with a maximum period of 6 years after sufficient steam is produced to bring the turbine up to speed and to synchronize the generator.

(*e*) *Indemnity.*—The Commission will indemnify Consumers against losses or damages arising out of the radioactive, toxic, explosive, or other hazardous properties of special nuclear materials.

(*f*) *Options to purchase.*—After completion of construction of the nuclear facilities, if Consumers fails to proceed with the project, the Commission has the right to purchase all of Consumers' interests in the overall facilities at a price to be agreed upon, but in no event to exceed the original acquisition cost less appropriate depreciation and less other pertinent considerations. If the Commission exercises its option to purchase, Consumers has agreed to purchase the power generated by the facilities if requested to do so by the Commission.

After 3 years from completion of construction of the nuclear facilities, Consumers have the right to purchase the Commission's interest in such facilities at a price representing the value of such property in the future production of power and other products.

(*g*) *Termination.*—The Commission may terminate for convenience of the Government at any time upon 30 days' notice, in which case payment would be made to Consumers in an amount equal to its capital investment in the reactor facilities less depreciation plus reimbursable costs incurred in conformance with the contract. Title to the facilities in question would then vest in AEC.

Consumers may terminate if it is unable to obtain satisfactory financing within 12 months from the date of execution of the contract. No payments will be made in the event of such termination.

(*h*) *Patents.*—In case an invention or discovery is made by Consumers in connection with the work under the contract, the Commission will receive a nonexclusive, irrevocable, royalty-free license for governmental purposes.

(*i*) *Licenses.*—The contract is considered one with and for the account of the Commission, and no licenses will be required, except for any byproduct or irradiation activities in which Consumers plans to engage.

(*j*) *Information and records.*—Consumers will provide the Commission with full technical and economic information which can be used by the Commission as it sees fit. The Commission and its representatives will have the right to inspect and audit the work, records, reports, information, data, and activities of Consumers under the project. The contract also includes the statutory GAO audit provision.

ARRANGEMENT NO. 58-111-2

A. Names of contractors

1. Prime contractor: Northern States Power Co., Minneapolis, Minn.
2. Principal subcontractor: Allis-Chalmers Manufacturing Co., West Allis, Wis.—for development, design, and construction of the reactor.

B. Description of proposed project

1. Objective: The objective of the proposed contract is to encourage private participation in the development of nuclear power technology and to accelerate the achievement of commercially feasible nuclear power. Under the contract, a nuclear reactor of an advanced boiling water type, designated as the controlled recirculation boiling water reactor (CRBR) designed to produce 66,000 net electric

kilowatts of energy will be constructed and operated by the Northern States Power Co. as part of its system.

2. Location: Site to be selected within the NSP service area (parts of Minnesota, North Dakota, and South Dakota).

3. Technical aspects (data are approximate):

Heat output: Reactor: 164 megawatts; superheater: 39 megawatts.
Electrical output: 66 megawatts.
Amount of fuel loading: 4,100 kilograms.
Enrichment percent, U-235: 1.6 percent.
Moderator: Water.
Coolant: Water.
Reactor outlet temperature: 489° F.
Reactor pressure: 600 psig.
Steam conditions: 500 psig, 825° F., exhausting at 1½ inches mercury absolute.
Byproduct utilization: None presently contemplated.

4. Estimated date of completion: June 30, 1962.

C. Estimates of cost

[In thousands]

Element of cost	Allocation of estimated costs		
	Total	AEC	NSP
1. Preconstruction research and development:			
(a) Performed by contractor	$5,000	[1] $5,000	
(b) Performed in AEC facilities	500	[1][2] 500	
2. Development, fabrication, and construction:			
(a) Reactor system:			
Research and development	4,000		[3] $4,000
Fabrication and construction	5,600		5,600
(b) Balance of plant:			
Research and development	200		[3] 200
Fabrication and construction	11,800		11,800
Subtotal, development, fabrication, and construction	21,600		21,600
3. Postconstruction, research and development	1,700	[1][4] 500	[3] 1,200
4. Waiver of fuel use charges		[1] 1,000	
5. Total value of AEC assistance		[1] 7,000	

[1] These are maximum amounts.
[2] Irradiation work and consulting charges by AEC.
[3] Research and development contributed in part by CUAPA members.
[4] Operating tests and inspection of fuel elements, etc.

D. General features of proposed arrangements

1. *Site.*—The site of the nuclear powerplant will be provided and selected by NSP and approved by the Commission.

2. *Construction.*—The nuclear powerplant will be constructed by NSP. Preconstruction research and development, design, fabrication, and construction will be subcontracted to Allis-Chalmers Manufacturing Co.

3. *Operation.*—NSP will operate the nuclear powerplant for 5 years as part of its interconnected system furnishing electric power service to parts of Minnesota, North Dakota, and South Dakota.

4. *Financial assistance.*—The Commission undertakes to furnish the following assistance:

Preconstruction research and development:	
Costs actually incurred by contractor	$5,000,000
Work and services furnished by AEC	500,000
Postconstruction research and development	500,000
Waiver of fuel-use charge	1,000,000
Total AEC assistance	7,000,000

NOTE.—The above figures are maximum.

NSP and 10 other electric utilities operating in the Midwest have formed a nonprofit corporation known as Central Utilities Atomic Power Associates (CUAPA). The 10 companies are to furnish a total of $3,650,000 to aid in the research and development program on this project and will receive training and technical information from the project. There will be no contractual relationship between CUAPA and the Commission.

Allis-Chalmers is to perform under subcontract, the preconstruction research and development, design, and construction of the nuclear powerplant. A substantial portion of its work will be on a fixed-price basis with NSP. To the extent, if any, that Allis-Chalmers costs on the work covered by the fixed price exceed the price Allis-Chalmers will be contributing financial assistance.

NSP will pay all costs associated with the project except as indicated above.

5. *Title.*—NSP will be the sole owner of the nuclear powerplant.

6. *Term.*—The term of the contract will extend until the expiration of 5 years after the issuance by AEC of a license to operate the facility, or 5 years after completion of construction of the nuclear powerplant, whichever is later.

7. *Indemnity.*—As a licensee of the Commission, NSP will be subject to the provisions of Public Law 256, 85th Congress.

8. *Option to purchase.*—In general, the Commission will have the right to purchase the nuclear powerplant if NSP fails to proceed with the project.

9. *Termination.*—The contract may be terminated by mutual agreement. NSP may terminate if it cannot obtain necessary licenses, regulatory agency approvals, or satisfactory liability insurance coverage.

10. *Patents.*—Title and all rights to inventions originated in connection with Commission-financed work will become the property of the Government with a nonexclusive, irrevocable, royalty-free license for NSP. On inventions originated under NSP-financed work, title will be in NSP, with a comparable license in the Government for Government purposes. All subcontract patent provisions will be subject to Commission approval.

11. *Licenses.*—NSP undertakes to obtain all necessary licenses from the Commission, and such other necessary approvals from Federal, State, and local regulatory agencies as are required to permit the construction and operation of the plant and the sale or use of the energy produced therein.

12. *Information and records.*—NSP will keep, and require its subcontractors to keep, records of technical, economic, and financial data developed in connection with the project and supply that information to the Commission for its use and dissemination. The Commission and its representatives will have the right to inspect and audit the work, records, reports, information, data, and activities of NSP and its subcontractors under the project. The contract will also include the statutory GAO audit provision.

ATOMIC ENERGY COMMISSION,
Washington, D. C., September 16, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: In accordance with section 111 (b) of Public Law 162, 85th Congress, I am transmitting herewith proposed cooperative arrangements with the Rural Cooperative Power Association, of Elk River, Minn., and the American Machine & Foundry Co. It is requested that these arrangements be considered by your committee along with those of the Consumers Public Power District of Nebraska and Northern States Power Co., Minneapolis, Minn., which were transmitted to you on September 13, 1957.

With respect to all three arrangements, the Commission requests that the committee waive, pursuant to its authority under section 111 (b), the 45-day period for which the bases of such cooperative arrangements are required to lie before it. This is essential in the present instance, since the American Machine & Foundry Co. agreement is contingent upon execution of a definitive contract no later than October 18, 1957.

Sincerely yours,

K. E. FIELDS, *General Manager.*

97670—57——2

Program Justification Data

ARRANGEMENT NO. 58-111-3

A. Name of contractors

1. Rural Cooperative Power Association, Elk River, Minn., for operation of reactor.
2. American Machine & Foundry Co., for research, development, fabrication, and construction.

B. Description of proposed project

1. Objective: The objective of the proposed contract is to bring new resources into the development of engineering information on the performance of nuclear power reactors and to advance the time when nuclear power becomes economically feasible. A closed-cycle boiling water power reactor (CCBR) designed to produce 225,000 pounds of steam per hour and 22,000 electric kilowatts of energy will be constructed by A. M. & F. under contract with the Commission. RCPA, under separate contract with the Commission, will provide the site and turbo-generating facilities and will operate the entire plant for 5 years as part of its system.
2. Location: Elk River, Minn.
3. Technical aspects (data are approximate):
   - Heat output: 58 megawatts (excludes superheater, 17 megawatts).
   - Electrical output: 22 megawatts (nominal).
   - Amount of fuel: 1,320 kilograms UO_2; 3,050 kilograms ThO_2.
   - Enrichment percent U-235: 9.8 percent.
   - Moderator: H_2O.
   - Coolant: H_2O.
   - Reactor outlet temperature: 533° F.
   - Reactor pressure: 900 pounds per square inch.
   - Steam conditions at throttle; 600 pounds per square inch at 825° F.
   - Byproduct production: None.
4. Estimated date of completion: August 1960.

C. Estimates of cost

[In thousands]

Element of cost	Allocation of estimated costs			
	Total	AEC	AMF	RCPA
1. Preconstruction research and development:				
(a) Performed in AEC facilities [1]	[2] 500	[2] 500		
(b) Fuel element development	[3] 915	[3] 915		
Subtotal	1,415	1,415		
2. Development, fabrication, and construction:				
(a) Reactor:				
Reactor plant (including superheater)	6,115	[3] 5,115	[4] 1,000	
Fuel for 1st core (including 15 percent spares)	[3] 1,400	[3] 1,400		
Conversion UF_6 to UO_2	300	300		
(b) Turbo-generating facilities	1,750			1,750
Subtotal	9,565	6,815	1,000	1,750
3. Operation:[5] Estimated cost to AEC	[6] 1,640	[6] 1,640		
4. Waiver of fuel use charge	125	125		
5. Total value of AEC assistance		9,995		

[1] May be performed in private facilities to extent feasible.
[2] This is a maximum.
[3] Subject to escalation not to exceed 5 percent.
[4] AMF retains as fee up to $300,000 of underruns on $5,115,000 total. AMF pays all overruns.
[5] Includes costs of training, RCPA consultations with A. M. & F., and other directly reimbursable work.
[6] After sale of steam to RCPA (in the event of excellent reactor performance the cost would be reduced or might even become a credit).

D. General features of proposed arrangements

1. *Direct contract with RCPA.*—

(*a*) *Site.*—Under the contract, RCPA will furnish the reactor site, which will be adjacent to RCPA's existing steam plant at Elk River, Minn. The Government's right to use the site for the purposes of this project will be assured by appropriate registration of the Government's interest, and by provision for rent-free lease following expiration of the contract term.

(*b*) *Construction.*—RCPA will furnish the turbine generator facilities without cost to AEC. AEC will provide the reactor plant.

(*c*) *Fuel elements.*—AEC will develop and furnish the fuel elements required for the initial core loading. The fabrication of subsequent fuel elements will be the responsibility of RCPA.

(*d*) *Operations; sale of steam.*—The basic principle of the arrangement is one of assuring that RCPA as a consequence of the undertaking, will incur no loss, and that it will make no profit while operating the reactor for AEC. The contract will provide for operation of the entire plant by RCPA and for the sale to RCPA of all steam produced by the reactor plant. The steam will be consideration for operating costs and vice versa; however, because the value of the two will not necessarily be equal, provision for adjustment to fulfill the "no loss-no profit" concept will be made as described below.

Instead of reimbursing RCPA directly for the costs of operating the reactor plant and receiving from RCPA specified prices for the steam it receives, the contract will provide for AEC to pay RCPA for those costs actually incurred in operating its system with the reactor plant in excess of the costs it would have incurred in operating its system with a conventional boiler of the same capacity at the same location. If RCPA's system costs with the reactor are less than its system costs would have been with a conventional boiler, RCPA will pay the difference to the AEC. The formula outlined will come into play once the reactor has achieved criticality. In arriving at RCPA's costs of operating the reactor as part of its system, costs incurred by it arising out of the nuclear character of the entire project will be taken into consideration. Thus the arrangement contemplates that RCPA will be made whole—that is, placed in the financial position it would have occupied if it had constructed the conventional plant it otherwise would have built. This arrangement permits the AEC to eliminate RCPA's risk of loss, while avoiding any operating subsidy.

In addition, AEC will directly reimburse RCPA for all capital costs it incurs for replacements and additions to the reactor plant, for the costs it incurs in the preoperation training program, for the cost of the A. M. & F. subcontract it had negotiated and prepared, and for services desired by AEC and performed prior to achievement of criticality.

For these purposes, AEC will obligate $1,640,000 at this time. Any further payment by AEC will be subject to the availability of funds.

(*e*) *Training.*—AEC will conduct, at the Government's expense, a program of training for up to 12 qualified employees of RCPA.

(*f*) *Term.*—The term of the contract will commence on the date of execution and will end 5 years after the acceptance of the reactor plant by AEC as being completed, tested, and operable.

(*g*) *Indemnity.*—AEC will indemnify RCPA against losses or damages arising out of nuclear incidents in a manner consistent with Public Law 256, 85th Congress.

(*h*) *Sale of the reactor plant.*—At the expiration or termination of the contract, the Government will, in accordance with law, offer to sell the reactor plant to RCPA pursuant to the provisions of Public Law 162, 85th Congress. The contract will provide that, if such offer is not accepted, AEC will have an option to lease the site of the reactor plant.

(*i*) *Termination.*—The contract will be subject to termination at any time by written agreement of the parties. Any such termination will be effective in the manner, upon the terms, and on the date specified in said agreement.

The Commission will have the right to terminate the contract (1) if it determines that the construction or operation of the reactor cannot be undertaken or continued without undue risk to the health or safety of the public (and the parties have not agreed to mutual termination), or (2) if, after the Commission has paid to the contractor the sum of $3,040,000 less costs incurred by the Commission for fabrication of the initial core loading (including spares), termination is desired for the convenience of the Government. In the event of termination by the Commission, the Commission will pay to the contractor, as full

termination costs, the costs for which the contractor is then entitled to direct reimbursement plus the net incremental expenses incurred in the operation of its system for such time subsequent to February 1960 as may reasonably be required by the contractor for the installation of a boiler plant using conventional fuels. The Commission has no present intention to exercise the right to terminate for convenience unless it finds that the economic and technical promise of the reactor for commercial utilization by RCPA or others is unfavorable.

(*j*) *Patents.*—In case an invention or discovery is made by RCPA in connection with the work under the contract, AEC will receive all rights.

(*k*) *Licenses.*—The contract will be considered one with and for the account of the Commission and no licenses will be required.

(*l*) *Information and records.*—RCPA will maintain accounts showing all costs of operating its system. RCPA will also provide the Commission with full technical, economic and financial information and reports and the Commission and the Comptroller General will have the right to inspect the work, records, reports, information, data and activities of RCPA under the project. AEC may use the information as it sees fit.

(*m*) *Approval by Rural Electrification Administration.*—RCPA has contacted the Administrator of Rural Electrification Administration and outlined the provisions of this agreement. RCPA was advised by the Administrator that these agreements, as he understands them, would not impair the feasibility of the REA loan and would be satisfactory subject to review of the final draft.

2. *Direct contract With A. M. & F.*—(*a*) *Construction and test operation.*—A. M. & F. will develop, design, fabricate, and construct the reactor plant (reactor and superheater) and perform 6 months of test operation by not later than August 1, 1960.

(*b*) *Training.*—A. M. & F. will conduct a program of training for RCPA's operators.

(*c*) *Title.*—Title to the entire reactor plant and the fuel elements, and superheater will be in the Government.

(*d*) *Indemnification against nuclear hazards.*—A. M. & F. will be indemnified by the Commission in the same manner as other similarly situated Commission contractors in accordance with the provisions of Public Law 256, 85th Congress.

(*e*) *Termination.*—The contract will be subject to termination at any time by written agreement of the parties, any such termination to be effective in the manner, upon the terms, and on the date specified in such agreement.

If construction of the reactor plant is made impossible by inability of A. M. & F. to obtain necessary licenses or regulatory agency approvals, A. M. & F. will have the right to terminate at any time, by written notice to AEC.

Neither the Government nor A. M. & F. will be required to reimburse the other or pay directly for any costs or expenses by reason of termination of the contract, other than costs, expenses, and commitments previously incurred by A. M. & F. for which it is entitled to reimbursement under the provisions of the contract.

The Commission will have the right to terminate the contract at any time for convenience of the Government. Upon such termination, A. M. & F. would be entitled to reimbursement for those costs, expenses, and commitments previously incurred by it for which it is entitled to reimbursement under the provisions of the contract, plus reasonable costs of termination, plus A. M. & F.'s million-dollar investment in the program, to the extent such investment has actually been made to the effective date of termination.

(*f*) *Patents.*—Title to all inventions made or conceived in connection with A. M. & F.'s portion of the project will become the property of the Government, with a nonexclusive, irrevocable, royalty free license for A. M. & F.

(*g*) *Licenses.*—This contract will be with and for the account of the Commission and no licenses will be required.

(*h*) *Information and records.*—A. M. & F. will keep, and require its subcontractors to keep, records of technical, economic, and financial data developed in connection with the project and supply that information to the Commission for its use and dissemination. The Commission and its representatives will have the right to inspect and audit the work, records, reports, information, data, and activities of A. M. & F. and its subcontractors under the project. The contract will also include the statutory GAO audit provision.

SEPTEMBER 14, 1957.

Mr. K. E. FIELDS,
General Manager, Atomic Energy Commission,
Washington, D. C.

DEAR GENERAL FIELDS: This will confirm the information phoned to you this morning to the effect that the Joint Committee will hold an open hearing on Tuesday afternoon, September 17, at 1:30 p. m., in room P-63, Old Supreme Court Chamber, in the Capitol, on the following subjects:

1. To consider the bases of the arragenments which the Commission proposes to enter into with the Consumers Public Power District of Columbus, Nebr., and the Northern States Power Co., submitted with the Commission's letter of September 13 and the bases of such other arrangements as the Commission may submit on or before the hearing date.

2. To obtain a status report on the Commission's other negotiations under the power-reactor demonstration program.

3. To consider the status of the Commission's work on project 58-e-14, gas-cooled reactor prototype; project 58-e-15, plutonium recycle experimental reactor; project 58-b-8, production reactor for special nuclear materials.

It is understood that you will appear, together with the Assistant General Manager for Research and Development and representatives of the Reactor Development Division.

We are notifying representatives of the private and publicly owned utilities, and equipment companies which are involved in the projects that they can attend the hearings and be heard if they so desire.

Sincerely yours,

JAMES T. RAMEY, *Executive Director.*

No. 99
September 16, 1957
For immediate release

From the Office of the Joint Committee on Atomic Energy:

Congressman Carl T. Durham, Democrat, of North Carolina, chairman of the Joint Committee on Atomic Energy, announced today that an open hearing will be held by the Subcommittee on Legislation on Tuesday, at 1:30 p. m., in room P-63, United States Capitol Building, September 17, 1957, to consider the bases of arrangements between the Atomic Energy Commission and certain electric utility companies for the construction and operation of nuclear-power reactors.

Specifically the subcommittee will consider a proposal of the Consumers Public Power District of Columbus, Nebr., with regard to a 75,000 electrical kilowatt sodium graphite reactor, and a proposal of Northern States Power Co., Minneapolis, Minn., for construction of a 66,000 electrical kilowatt boiling water reactor. AEC advised they also may be ready to submit the bases of arrangements with Rural Cooperative Power Association of Elk River, Minn., for a 22,000-kilowatt boiling water reactor in time for the hearing.

Chairman Durham stated that the bases of arrangements between the Atomic Energy Commission and the first two companies were submitted by the AEC to the Joint Committee on Atomic Energy Friday afternoon, September 13, and the hearing was being held in order that consideration can be given to the possibility of waiving the normal 45-day waiting period and thereby permitting the signing of contracts as soon as possible. By law, unless waived by the committee, these contracts cannot be signed by the AEC until the bases for them have been submitted and lie with the committee for 45 days while Congress is in session.

Representative HOLIFIELD. In terms of procedure today, I believe, it will be helpful for the committee to lead off with an introductory statement by General Fields, together with an explanation by Commission representatives of the three agreements.

Following this explanation, if representatives of the utilities or the equipment company involved wish to make any comments we will be glad to hear from them. We understand that Mr. Schacht, of the Consumers Public Power District of Columbus, Nebr., would like to make a statement.

We understand Mr. Connell, of Senator Humphrey's office, will make a statement.

After these gentlemen have testified we would then expect that any others who wish to comment on the matters might be heard.

In that connection, we understand that representatives of some of the Nebraska cooperatives would like to be heard.

At this time, General Fields, we will ask you to proceed with such statement as you wish to make to the committee.

STATEMENTS OF GEN. K. E. FIELDS, GENERAL MANAGER; LOUIS H. RODDIS, JR., DEPUTY DIRECTOR, DIVISION OF REACTOR DEVELOPMENT; DELMAR M. MORRIS, ASSISTANT DIRECTOR FOR ADMINISTRATION, DIVISION OF REACTOR DEVELOPMENT; E. J. BLOCH, DIRECTOR, DIVISION OF PRODUCTION; DON S. BURROWS, CONTROLLER, DIVISION OF FINANCE; EDWARD DIAMOND, DEPUTY GENERAL COUNSEL; AND A. TAMMARO, ASSISTANT GENERAL MANAGER FOR RESEARCH AND INDUSTRIAL DEVELOPMENT

General FIELDS. Thank you, Mr. Chairman.

As you will see, I have a brief opening statement I would like to make. As you will see in this statement, I am modifying our one request to you which is a request for a waiver in the instance of the arrangements on the Rural Cooperative Power Association power proposal, in view of some developments that occurred just this morning, and I will touch on them, sir, in my statement.

Representative HOLIFIELD. You may proceed.

General FIELDS. It is a pleasure to be here today to ask your committee to waive the 45-day requirement of section 111 (b) of Public Law 162, 85th Congress, with regard to 2 cooperative arrangements under the Commission's power demonstration reactor program. I have a number of my staff with me who, I believe, will be able to answer any questions you may have when I have completed by brief introductory remarks.

As you well know, the Commission has issued three separate invitations for participation in its power demonstration reactor program. In connection with the first round invitation, three proposals were initially submitted to the Commission. Two of the three proposals, those made by Power Reactor Development Co. and Yankee Atomic Electric Co., have resulted in executed, definitive contracts with the Commission. The third proposal, that of the Consumers Public Power District of Columbus, Nebr., is now before your committee for consideration.

On January 7, 1957, the Commission issued the third invitation in connection with its power demonstration reactor program. Three proposals have been received to date, and the Commission has accepted one of these, that of the Northern States Power Co., as a basis for negotiation of a definite contract.

On September 13, 1957, in accordance with the requirements of Public Law 162, the Commission transmitted to the joint committee the bases for the proposed arrangements with Consumers Public Power District and with Northern States Power Co. We believe that

these submittals comply in every way with the requirements of section 111 (b) of that act. With respect to Consumers, the arrangement is confirmed by a certified copy of excerpts from minutes of meeting of August 30, 1957, of the Consumers board of directors, transmitted to the Commission on September 3, 1957.

The arrangement with Northern States is confirmed by a letter dated September 6, 1957, from Earl Ewald, vice president in charge of operation, Northern States Power Co., to W. Kenneth Davis, Director, Division of Reactor Development.

In the Commission's September 13, 1957, transmittal letter to the Joint Committee, we informed you that we had not been able, as of that date, to reach a final agreement with the Rural Cooperative Power Association of Elk River, but that negotiations were continuing and we were hopeful that we would be able to submit the basis for the arrangement with RCPA to the committee prior to the date of this hearing.

Yesterday, September 16, 1957, that basis of arrangement was transmitted to your committee. It incorporated a description of the arrangement which the Commission had with the American Machine & Foundry Co., the prime design, development, fabrication, and construction contractor for the Elk River reactor plant. The basis of agreement with RCPA was confirmed by a letter dated September 14, 1957, from Edward Wolter, general manager, Rural Cooperative Power Association of Elk River, Minn., and the basis of agreement with AMF was confirmed by a letter dated September 15, 1957, from Roy Snapp, divisional vice president, American Machine & Foundry Co.

The Commission had prepared telegrams to both RCPA and AMF accepting the bases of the arrangements sets forth in their letters to the Commission and was ready to transmit these last night, September 16, 1957, when a telephone call from Mr. Snapp, representing AMF, informed us that the company was not prepared to proceed on the basis of the ceiling price previously agreed to. We understand we are being advised formally of this by telegram. In view of this development, and because the arrangements with RCPA and AMF are necessarily interrelated, we were unable to transmit our telegram of confirmation to RCPA.

Because of these circumstances, I called Mr. Durham and Mr. Holifield, and I say "you" in my statement. I actually called Mr. Durham, whom I thought was going to chair the meeting. I called Mr. Durham this morning and also Mr. Ramey, to withdraw our request to your committee to waive the 45-day waiting period with regard to the proposed RCPA arrangement. This does not mean that we are abandoning this project; it only means that the Commission needs an opportunity to consider what steps it will take next. In no event will be be able to complete alternative arrangements before the end of October, and in view of that, we see no need for leaving the waiver request in effect at this time.

I doubt that we will be able to complete alternative arrangements either with AMF or someone else before the end of October, and in view of that, we see no need for leaving the waiver request in effect at this time. As a matter of fact, we do need to review the project in this light completely, as well as to consider other means to proceed.

I would add to this statement that I received at 12:30 today a copy of what will be delivered in telegram form from Mr. Snapp confirming this, and in effect as being for a considerable increase in the ceiling price that we had considered before.

Representative HOLIFIELD. Do you have that ready to submit for the record?

General FIELDS. I have it in draft form. I have had a short time to review it. I can tell you what it relates to, and I can submit it for the record, yes, sir; but not right at the moment I don't believe. I do have a rough draft of it here. It has come through in a dictated form.

(The telegram referred to follows, together with a subsequent statement by the American Machine & Foundry Co. requested on p. 62, and a subsequent letter from AEC regarding developments since the hearing:)

COPY OF TELEGRAM TO AEC, RECEIVED 1:26 P. M. SEPTEMBER 17, 1957, FROM AMERICAN MACHINE & FOUNDRY CO.

On September 14, 1957, AMF authorized transmittal to AEC of a letter outlining certain tentative understandings regarding construction of a boiling-water reactor at Elk River, Minn., subject to later completion and execution of a definitive contract. AMF has reconsidered and reappraised further the unlimited financial liability which it will incur under the proposal in this pioneering field and has concluded that the risk of losses to AMF stockholders will undoubtedly greatly exceed the $1 million investment which we have already made in this project and have continuously offered to make for furtherance of the power-reactor program in small reactors. Nevertheless our interest in this program remains as great as it was at the time our initial proposal was made. We, therefore, ask that the following change be made in the above letter and request that you seek approval from the Joint Atomic Energy Committee as part of our understanding. As you know, the contract is a cost-type contract without fee, unless the final cost is less than the present ceiling (as specified). This we propose not to change. The contract should have a ceiling recaste in the light of the most recent reactor cost "experience" which have emerged during negotiations. We believe that reactor-cost experience (including research and development) show ranges from $750 to $1,000 per kilowatt in reactors of greater power than the Elk River reactor and that smaller powered reactors range from $1,500 to $2,000 per kilowatt, we, therefore, feel that the present ceiling at $562 per kilowatt is inadequate and inequitable in view of the "cost without fee" type of contract. The figure of $562 per kilowatt is derived as follows: Ceiling $8,930,000 less $500,000 for superheater (to produce 7,000 kilowatts out of total 22,000 kilowatts) equals $8,430,000 divided by 15,000 kilowatts, or $562 per kilowatt. (The present ceiling was arrived at 9 months ago and we have been denied all requests for adequate revision.) We feel that a fair ceiling would lie somewhere between the ranges but, in view of our hope that a quick approval may be obtained, we have selected for this offer the lowest figure in the range ($750 kilowatt). By the above formula we obtain a ceiling of $11,750,000 as follows: $750 times 15,000 or $11,250,000 plus $500,000 for superheater (7,000 kilowatts) or $11,750,000. We do not believe that the Joint Atomic Energy Committee, in enjoining the AEC to "maintain existing economic advantages" in second-round contracts, meant that ceilings should be maintained which at the time of signing the contract are clearly so inadequate that the contractor must lose money over and above his set "contribution."

SEPTEMBER 18, 1957.

Hon. CHET HOLIFIELD,
Chairman, Subcommittee on Legislation,
Joint Committee on Atomic Energy,
The Capitol, Washington, D. C.

DEAR MR. HOLIFIELD: This letter is in response to your invitation yesterday to Mr. Roy B. Snapp, vice president and group executive for the atomic-energy group of American Machine & Foundry Co. to submit a statement for the record of the

hearings before your subcommittee on the matter of the increase in cost estimates for the boiling-water reactor to be built at Elk River, Minn.

First, I want to express our extreme regret that the decision on the ceiling costs of the AMF proposal had not been reached in time to permit an adequate presentation to the Atomic Energy Commission prior to the appearance of representatives of the Commission in connection with the request for a waiver of the 45-day requirement under section 111 (b) of Public Law 162, 85th Congress. Accordingly, the Commission felt it necessary to withdraw the request for the waiver of the time requirement with regard to the nuclear powerplant for the Rural Cooperative Power Association of Elk River, the initiating sponsor of the project.

I trust the members of your subcommittee did not interpret this action as indicating withdrawal of our proposal. We are seeking an immediate review of the original cost estimates with the Commission staff and hope very much that the proposed new philosophy reflected in our revised proposal can be accepted by the Commission as a sound basis for a definitive contract.

In brief, we asked that the Commission increase our cost estimate from $8,930,000 to $11,750,000 for research and development, design, construction, fuel-element manufacture, test operation, and operator training. We propose to pay up to $1 million of this amount.

As you know, the proposal is for a cost-type contract without fee. We seek no change in this arrangement.

We have consistently opposed the principle of cost ceilings for this type of developmental project. We believe that the manufacturer's contributions should be straightforward, as in the case of our million-dollar offer, and that the true nature of forward cost estimates for research and development work be recognized as not properly applicable for fixed limitations.

But whenever the so-called ceiling limitation is imposed, it should be determined from the most recent cost experience available. As far as we have been able to determine, the actual power reactor cost experience to date, including research and development, shows ranges from $750 to $1,000 per kilowatt of electrical output in reactors of greater power than the Elk River reactor, and from $1,500 to $2,000 per kilowatt for reactors smaller than Elk River.

If one excludes the nonnuclear energy input from the superheater, the per kilowatt cost of the Elk River reactor is $562 under the original estimate and $750 under the new estimate. We actually arrived at our new estimate by selecting the lowest figure in the range of actual recorded experience with power reactor costs.

This seems to be a very reasonable procedure, inasmuch as no data is available to us indicating that anybody has been able to build a power reactor at lower cost. We have asked the Commission to sit down with us and help us to come to a determination of the proper estimates through a complete analysis of the mass of cost data accumulating throughout the atomic power development program.

We understand the very serious concern with which the members of the Joint Committee may be expected to view the inevitable delay in the start of construction of this project, we share the Commission's determination to have a test demonstration of this reactor system at the earliest practicable time, and we understand the disappointment of the members of the Elk River Cooperative. In the face of these urgencies we were forced to recognize that no other course was open to us.

As indicated in the testimony of Mr. Kenneth E. Fields, General Manager of the Commission, the change in our position was made abruptly, between the time of delivery of a letter outlining our general understandings on Saturday, September 14, and the morning of the 17th, when we notified the Commission of our reconsideration and reappraisal of the project and asked that changes be made in the cost ceilings.

We felt compelled to make this sudden change on the basis of three major factors. Perhaps none would have been compelling alone, but taken together they constitute adequate justification for the submission of new cost figures. In view of the almost national interest in the project, the clearly demonstrated desire of the Joint Committee to speed the project, and the basic objectives of the Atomic Energy Commission for small reactors in the power demonstration reactor program, we decided to ask for an increase in the prices only after the most thorough and thoughtful consideration at the highest corporate level.

97670—57——3

The three major factors were—

1. The risk of losses to the company threatens to exceed substantially the million-dollar contribution which we propose to make to this project and, in fact, have already invested.
2. The cumulative cost experience with other power reactors already built and operating, or nearing completion, is the most dependable cost data available to us and we cannot in conscience and responsibility ignore it.
3. We determined that the policy objectives of the national atomic energy program as defined in the Atomic Energy Act of 1954 and as expressed by the Commission for the establishment of an atomic power industry on a sound economic basis, could be best served by a forthright acknowledgment of the economic facts which confront us and a determined effort to conduct all developmental operations on the most realistic cost basis possible.

As we told the Commission on September 17, our interest in this project remains as great as it was at the time our initial proposal was made. We believe it is important to the Nation's atomic power development program that the system designed for Elk River should be carried through to full scale test. This will be the first thorium-fueled boiling water power reactor and is of unique technological interest. We believe that this reactor concept should be pursued without regard as to who may be selected as the contractor.

In response to your direct question as to whether the assignment to the Commission under Public Law 162 of new contracting responsibilities for this and other projects has anything to do with our cost changes, the answer is no.

As a matter of fact, we see the new contracting arrangement as decidedly advantageous from the standpoint of the cost to the Government, as well as from the standpoint of the Elk River Co-op as sponsor. From our own standpoint, the direct contract relationship with the Commission is simpler and consequently should mean lower costs and more expeditious conduct of the project.

The underlying reasons for my feelings on this point had been fully brought out during the course of the negotiations. In part, our final decision to change the ceiling figures was a result of the refusal by the Commission to give adequate consideration to what your committee has described as "some protection of the equipment manufacturer for increases in cost arising out of developmental problems beyond its control * * * provided on a cost-sharing basis."

Since assuming its new role under Public Law 162, the Commission has had no occasion to reappraise our proposal from the perspective from which we now seek to have it considered.

The reappraisal which we have made, and which we now ask the Commission to make, is from the perspective that it simply does not make sense—for the Commission, for the public, nor for the concerned contractor—regardless of high motives in patriotism and public service, to carry out an important developmental project such as this one under any conditions other than those which will preserve and strengthen the capabilities of the contractor for future work in the field.

One of the declared purposes of the basic atomic energy law of the Nation is to strengthen free competition in private enterprise. "Buying in" to a developmental project through a cost-absorbing proposal impossible for competitors of lesser resources, with a view to future recovery of losses, is not in keeping with the spirit of the law, and we do not believe it makes sense from any standpoint. It is my firm belief that the Congress, the Commission, and the American people want the national atomic power development program to go forward on the soundest possible basis, with full recognition and disclosure of the cost facts.

I believe it is of the utmost importance to the progress of the Commission's program that all of the developmental projects be financed on a basis of full consideration of the requirement for a sustained effort over a period of many years. Otherwise, it will not be possible for American industry, perhaps with the exception of a few of its giants, to continue at high levels the developmental effort that is clearly called for if America is to maintain its position in the field of atomic energy.

Please accept my apologies if the circumstances of this change have in any way inconvenienced the Committee. I am aware of the extent to which our action has affected the Commission's plans, and I would like to assure both the Joint Committee and the Commission that we will do everything in our power to make up for the lost time.

Thank you for this opportunity to submit a statement of our position. If there is any additional information which the members of the Committee or its staff may desire, we will be happy to supply it.

Yours very truly,

MOREHEAD PATTERSON, *Chairman.*

ATOMIC ENERGY COMMISSION,
October 8, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: The purpose of this letter is to inform you of the developments which have taken place on the Elk River situation subsequent to our last meeting with your Committee on September 17, 1957. You will recall that just prior to that meeting, I received word from Morehead Patterson, chairman of the American Machine & Foundry Co., which nullified the previous AEC-AMF understanding and proposed a new ceiling cost to the Commission of $10,750,000 for the development and construction of the demonstration power reactor for the Rural Cooperative Power Association. I am sure that this action has proved as disappointing to the Joint Committee as it has been to the Commission. Had AMF adhered to their agreement, we fully expected to execute a contract within short order, subject to the waiver by the Joint Committee of the 45-day waiting period.

During the past 3 weeks we have been in constant contact with AMF in an attempt to reach agreement on a revised basis. In their most recent proposal, AMF would assume, in addition to the previously agreed-to figure of $1 million research and development cost, a 25-percent share of any cost overrun beyond $8,930,000 up to a total AMF overrun liability of $1.2 million, with AEC to assume any excess beyond that figure. The Commission has declined to accept the open-ended responsibility which this proposal requires and has decided to issue a general invitation for bids for a cost-type, maximum ceiling price, contract for the RCPA power-reactor system. We plan to announce this invitation very shortly, with the details of the invitation to be issued soon thereafter.

In the general invitation for bids, we will ask the contractor to—

(*a*) Undertake design, development, fabrication, construction and initial startup of a closed-cycle, boiling water reactor and its necessary appurtenances, including first core and separate fossil fuel-fired superheater, suitable for installation in the RCPA system and capable of generating 22,000 kilowatts of net electricity.

(*b*) Test operate the plant.

(*c*) Train RCPA operator personnel.

The invitation will ask that bids indicate a maximum ceiling cost to the Commission. A ceiling level will not be specified. Bids are to be submitted within 90 days of the invitation and the Commission is to be notified within 30 days of intent to bid.

There has been no lessening of our conviction that the installation and operation of a low-power, closed-cycle boiling water reactor in a commercial system would make an important contribution to the attainment of economic nuclear power. We believe, however, that there is a reasonable probability of achieving this goal at a lower cost to the Government than is represented by the AMF proposals. To our knowledge, other equipment manufacturers are keenly interested in developing a market for boiling water reactors and, through the adoption of component design, fuel element configuration, or reactor structure differing from those contemplated by AMF, may succeed in accomplishing the objective at a lower cost.

We have been in touch with the Rural Cooperative Power Association on these recent developments. They have agreed to hold open their offer to participate with the Commission in a demonstration project essentially on the same terms as contained in our present agreement.

Sincerely yours,

R. W. COOK, *Acting General Manager.*

General FIELDS. As you can see, I am still awaiting a formal delivery of the telegram. It does say that they will be unable to proceed for reasons that they feel that the cost experiences to date are such that the ceiling should be raised.

You see, this arrangement was on a cost basis with AMF with a ceiling price in it. If the cost of the construction went above that ceiling price, this was to be a cost that they would then have to absorb. They accepted the ceiling-price arrangement in a cost-type contract but they feel that they need something like $3 million more in the construction for this.

Representative HOLIFIELD. What was the original estimated cost?

General FIELDS. The first proposal, I think we have that here, was a little over $3 million. I will have to check that. I will have to supply it for the record, sir. The first proposal is different than what we submitted to you yesterday and it was less even than submitted then.

(The information referred to follows:)

Mr. A. V. Peterson, vice president of AMF Atomics, Inc., in a letter to the Rural Cooperative Power Association, dated November 17, 1955, quoted AMF's estimated total price for design, construction and preliminary operations as $2,985,000. He also quoted the guaranteed maximum price for the complete engineering and construction of the reactor plant as $3,760,000.

Representative HOLIFIELD. On the second round I have a proposal here dated June 19, that is, a staff memorandum dated June 19, with analysis of all of the cooperative arrangements. This particular staff submitted an estimated total plant cost of $8,136,000. The reactor and superheater by AEC, at $5,686,000. There was a site and related facilities value by RCPA, $700,000, and electrical generating facilities, $1,750,000 by RCPA. That made a total of $8,136,000.

Now, I believe that is what you submitted to the committee during the hearings; is it not?

General FIELDS. I believe it is; yes, sir.

Representative HOLIFIELD. That was raised over the original estimate?

General FIELDS. Yes. You asked me to the original and I will have to check that. The $3 million, as I recall it, for the reactor plant itself was there, and there are other costs that total the $8 million figure you are quoting.

Representative HOLIFIELD. The reactor as submitted here was $5 million?

General FIELDS. I think the $5 million figure is the one that relates back to the original estimate which was $3 million to $3.5 million against the $5 million, and I believe the other factors are approximately the same as in their original proposal.

I would like to confirm this for the record.

Representative HOLIFIELD. You tell the committee now that they are asking for about $3 million increase over the $5,686,000?

General FIELDS. Yes, sir.

Representative HOLIFIELD. Is that a firm price, or is that something else?

General FIELDS. It is proposed that this would be a ceiling on a cost-type contract with them. Thus, if they went over the total amount of this new ceiling, that would be a fixed bid for that amount.

If the costs were actually less, since it is a cost-type contract, then it would be less to the Government than this ceiling price.

Representative HOLIFIELD. On page 203 of the hearings, the figure of $3,760,000 was given for the reactor.

General FIELDS. I believe that is the one I referred to.

Representative HOLIFIELD. Later it was raised to $5,686,000, which was presented to us also at that time as a raise. Currently it was the estimated cost. Is it the $3 million figure that they now request, or is it more?

General FIELDS. The total in the ceiling overall, you see there are several items in this total for AMF to perform—as I understand it on quick reading of this, it is that this new ceiling is something like $3 million over the old ceiling that they would like in their contract.

Representative HOLIFIELD. That would bring it up in round figures to around $11 million.

General FIELDS. That is true.

Representative HOLIFIELD. Are there any other differences in their proposal?

General FIELDS. I haven't had time to analyze it, Mr. Chairman, but that is the significant one. As I understand it, they do accept all of the other provisions that we have negotiated with them on this.

Representative HOLIFIELD. We were told repeatedly during the debate, and I remember Senator Thye, of Minnesota, saying on the floor that this was lying on the desk of the AEC, and all it needed now was a go-ahead signal, and they were ready to sign. Something has happened in the meantime, apparently. What has happened in the last 6 weeks? What would cause them to change their mind on that?

It is about 3 weeks, I guess it is. What has happened to change the picture? Has there been any less advantageous terms offered to the Elk River people or to the AMF than was offered to them before?

General FIELDS. I don't believe that there have been any changes in these terms.

Representative HOLIFIELD. The Commission hasn't made any tighter requirements on them, have they?

General FIELDS. Not that I am aware of. As a matter of fact we went back to them on the basis required in the authorization act where we would have the contract as between the Commission and AMF rather than as between Elk River and AMF which was the basis upon which we had been proceeding, as late as yesterday we thought we had an agreement as between the three parties.

Representative HOLIFIELD. There was no objection on their part to dealing directly with the Commission?

General FIELDS. I am not aware of any.

Representative HOLIFIELD. They didn't state any objection? This change, then, of the amount has nothing to do with the legislation?

General FIELDS. Mr. Chairman, I cannot speculate as to what led to this change in the last 24 hours, not having had the opportunity to discuss it completely, to any extent, really, with the AMF representatives.

Representative HOLIFIELD. In your opinion, this is going to be a forerunner now of all of the rest of these cooperative arrangements? Do you think this is the beginning of a pull-out on the part of the manufacturers from going ahead on their contracts?

General FIELDS. I hope it is not. We have had, of course, the instance of the Wolverine contract.

Representative HOLIFIELD. Let us hear about that. What was that?

General FIELDS. This is somewhat similar, where the Foster-Wheeler Co. found that they could not proceed on the basis of the costs that they had estimated for the construction of the reactor for that purpose.

Representative HOLIFIELD. What was that?

General FIELDS. So they withdrew their offer.

Representative HOLIFIELD. What was the price that they had agreed upon as presented to us?

General FIELDS. Roughly $5 million as I recall, Mr. Chairman. They wished to increase this very substantially for this reactor to the neighborhood of $14 million.

Representative HOLIFIELD. We have here, under the same date of June 29, a reactor cost by the AEC of the original $2,835,000, and currently estimated cost at that time, on page 203 of the hearings was $3,837,000. As I remember this, this was the Wolverine Cooperative up in Michigan which showed a profit of $18,000 on their last year's operations.

Now they are raising their estimate on that from $3,837,000 to how much?

General FIELDS. I am not sure they are corresponding figures. The comparable figures that I have, Mr. Chairman, on August 23 to the joint committee were that the authorization for appropriations was $5,472,000, and the company now states it is prepared to undertake the work on a cost reimbursement basis only, and further estimates that that would now total $14,426,000.

I would have to look through the records to find the compilation of this $5,472,000 but it is substantially for all of the work that Foster-Wheeler was to do under that proposal.

Representative HOLIFIELD. The first submission, did you say, was $5,400,000?

General FIELDS. Yes; that was the authorization.

Representative HOLIFIELD. That was a flat price, wasn't it?

General FIELDS. It was a ceiling price arrangement, I believe, in that instance, too.

Representative HOLIFIELD. That was a flat ceiling price?

General FIELDS. Yes, sir.

Representative HOLIFIELD. And I think it included some post-construction research and development, didn't it?

General FIELDS. That was not in the $5 million, it was a separate item and I would have to recheck the data sheets here.

Representative HOLIFIELD. I was trying to harmonize the figure of $3 million with that.

General FIELDS. I cannot do that without additional records here, sir.

Representative HOLIFIELD. It was $3,887,000, and I was trying to reconcile that with the figure you used. I felt it was different in that it was possibly construction development and research.

General FIELDS. It may be.

Representative HOLIFIELD. That has gone up three times and that is no ceiling price, that is an open-end contract.

General FIELDS. That is what they indicate would be the basis upon which they would have to proceed, if they proceeded. We have now under consideration some studies being performed of this by one of our contractors, to determine what course of action we think we will take with respect to Wolverine and we have not yet made such determinations.

Chairman DURHAM. What do you attribute the increase of cost to, on these items? Is it lack of experience in bidding on this sort of thing?

General FIELDS. I think that had quite a bit to do with it, yes, Mr. Chairman. We have had cost increases along the way quite a bit, and some of this may be overoptimism at that stage, or inexperience, and I don't know. I need to analyze this more carefully.

Chairman DURHAM. What are you doing with Wolverine at the present time? Are you negotiating with them?

General FIELDS. We are not negotiating with them at the moment.

Chairman DURHAM. You are not?

General FIELDS. No, sir. We are taking a look at this, and determining on the basis upon which we think it would be technically an attractive project, before we determine what course to take with respect to it.

Chairman DURHAM. What type of reactor is that?

General FIELDS. This was a so-called homogeneous, but a so-called burner upper, one region reactor which would burn uranium 235.

Chairman DURHAM. Is anybody else at the present time building that type?

General FIELDS. I don't believe so. We have a reactor experiment at Oak Ridge.

Chairman DURHAM. What about Elk River?

General FIELDS. That is a boiling water reactor.

Chairman DURHAM. You do have that type?

General FIELDS. There are several of those in various use stages and types. There are actual reactors, powerplants.

Chairman DURHAM. But the Elk River is entirely a new concept?

General FIELDS. No, sir; it is not. It is a boiling water reactor, and we have a boiling water powerplant at Argonne, General Electric has one that is built at Vallecitos, which is slightly different. This has a different cycle to it, an adaptation to it that has some attractive features that we think on a basis that we originally proposed this in conjunction with the authorization hearings, we felt it was a desirable addition to the reactor program. We still do on that basis. I should say that. Whether we will on a $3 million increase, I don't know. I haven't had time, since I got this, to even form in my own mind what I would recommend to the Commission if it had to be on the additional $3 million basis.

Chairman DURHAM. Would that require new authorization in the law?

General FIELDS. I am not sure. I am not sure whether this falls within the 15 percent latitude or not. I haven't had time to even consider that, Mr. Chairman.

Chairman DURHAM. I shouldn't think it would.

General FIELDS. Probably in the overall, it might fall within that limitation. We would still have to submit it to the Joint Committee

for the 45-day period or waiver but whether it requires additional new authorization would depend upon the actual total amount, and whether it fell within the latitude allowed there. But in the light of this, Mr. Chairman, we regret it, and I am sure that the Rural Cooperative Power Association whom we have been working with very closely and who have been very cooperative in proceeding and attempting to reach agreement here regrets it also. I think it has been going along excellently, and it is unfortunate that this has developed.

I can understand that at the last minute there may be considerations on the part of the AMF that overrule what they were proceeding on in good faith before. But since it has come up at the last juncture, I am not in a position, or the Commission is not, either, to come to you and ask for a waiver of this at this time. I think that we need time to review it and by the time that the committee can reconvene again, if they can, say, late in October or something, I would hope we would have this fairly clear in our mind as to how we wished to recommend that we proceed on it.

Representative HOLIFIELD. Well, we are present here with two of the cooperatives. How about the Piqua and Cugach? Have you heard from them? Are the people doing that work ready to ask for 2 or 3 times increase in their estimate?

General FIELDS. Not that I know of, Mr. Chairman. We have sent to Piqua and Cugach, a questionnaire designed to elicit more detailed information concerning their conventional operating costs, and in each of these cases, as you know, there is development work proceeding with respect to the contracts rights now. We have not as yet heard back from them in response to this questionnaire so that we haven't moved forward any further than that with respect to them. But there is development work on both of these going forward, as you know.

Representative HOLIFIELD. What is the date of the questionnaire that you sent out?

General FIELDS. We have been in touch with them before, but it was sent out on August 22, sir.

Representative HOLIFIELD. The committee would like to know if the change in the law has had anything at all to do with this revision of price on the part of the manufacturers.

General FIELDS. I cannot answer that. I have no opinion on that at this moment, sir.

Representative HOLIFIELD. Well, has it changed the power of the Commission to make a less advantageous deal, you might say, for the Government?

Has it caused this increase from $5 million to $14 million in the estimated cost of the Wolverine plant?

General FIELDS. I don't believe that you could say that the law has resulted in that change. At least that is my preliminary opinion, sir.

Representative HOLIFIELD. Would it be fair for the committee to draw the inference that after negotiating for from 18 to 24 months, that when you got to the point of actually putting the signature on the line, that you found out that you weren't as near ready to go ahead as you thought you were during the time of the consideration of the legislation for authorization?

General FIELDS. I don't believe so, sir. It is not in the case of the Elk River arrangements. Up to yesterday we were all ready to sign contracts with the information we had.

Representative HOLIFIELD. There was no action on your part, then, or no indication on your part to the machinery manufacturers that caused them to take this action?

General FIELDS. I don't believe so.

Chairman DURHAM. You were ready to sign the contract at the original cost?

General FIELDS. On the basis of the arrangement we had submitted to you as of Monday, yes, sir.

Representative HOLIFIELD. There was no communication from the Commission to the manufacturers in any way which caused them to revise their prices?

General FIELDS. Oh, absolutely not, Mr. Chairman. We have had negotiations with them, and we have been doing so on a basis of the arrangements as described in that letter yesterday to you.

Representative HOLIFIELD. So the decision of AMF Elk River came as a surprise to you yesterday?

General FIELDS. Yes, sir.

Representative HOLIFIELD. All right. Will you finish your statement, then.

General FIELDS. The two arrangements which now therefore lie before your committee are the result of detailed discussions between the respective parties and represent agreement of the parties to the principles underlying each arrangement. Definitive contracts respecting the two arrangements are in various stages of negotiation, and we anticipate that they will be ready for execution in the near future. Our letters of submittal dated September 13, 1957, and September 16, 1957, formally requested the joint committee to waive the 45-day period for which section 111 (b) of Public Law 162, 85th Congress, requires these cooperative undertakings to lie before it. We hope that our appearance here today will enable the committee to grant such a waiver with respect to the Consumers and Northern States, arrangements so that the parties may proceed to execute definitive contracts as expeditiously as possible.

The committee may recall that in the Commission's September 13, 1957, transmittal letter covering the arrangements with Consumers and Northern States the Commission pointed out that a recent opinion of the Comptroller General of the United States relating to materials procurement contracts had raised some doubts about the Commission's authority to enter into long-term contracts. Commission personnel met with representatives of the General Accounting Office, and we have on several occasions, but on September 12, 1957, specifically, we made a formal submittal of the Consumers arrangement to the Comptroller General on that day and of the Northern States arrangement on the following day. We have not, as yet, had any opinion from the Comptroller General on either of these formal submittals, but the General Accounting Office has them under consideration. If you so desire, I shall ask Mr. Diamond, the Commission's Acting General Counsel, to explain the nature of the problem to you.

Representative HOLIFIELD. I think that would be in order, because you are asking the committee to grant you a waiver on an arrangement which the Comptroller General has not rendered an opinion on, as yet, and when in fact such contacts as you have had with him have been of the nature of questioning your right to make that contract. I think we would like to hear from Mr. Diamond.

Mr. DIAMOND. As Mr. Fields just pointed out, we have submitted formal letters to the Comptroller General, requesting his opinion as to the validity of the proposed arrangements with Consumers and Northern States.

Representative HOLIFIELD. Under what date did you submit that?

Mr. DIAMOND. These were submitted I believe on September 13 and 14. I think those are the right dates.

Representative HOLIFIELD. September 13 and 14?

Mr. DIAMOND. One was sent on the 12th and the other on the 13th.

Representative HOLIFIELD. You were aware of this problem long before this. You were aware of this problem when Congress was in session, weren't you?

Mr. DIAMOND. I might say the problem arose originally in connection with the proposed procurement of magnesium. The question arose about 6 months ago when we submitted a letter to the Comptroller General in connection with that procurement. We received a reply in which the Comptroller General stated we didn't have the authority to enter into that arrangement. We then resubmitted the question because of the broad implications of the opinion that he wrote. We only received a reply to this resubmission from the Comptroller General within the last month.

Representative HOLIFIELD. On the magnesium contract?

Mr. DIAMOND. Yes, sir. He confirmed his earlier opinion and made some other statements that had implications that seemed to involve the type of arrangements that we were contemplating here, at least the principles were broad enough to raise some question.

Chairman DURHAM. Did you actually submit a draft of the contract or just the arrangements to the Comptroller General?

Mr. DIAMOND. We submitted draft contracts, at least in one case we submitted a draft contract.

Representative HOLIFIELD. How can you in good faith come before the committee and ask us to waive an arrangement which is under consideration by the Comptroller General and has not yet been decided to be in order?

Mr. DIAMOND. It is my opinion that the arrangement is a valid one, particularly in the light of the legislative history. Moreover, we have had informal conferences with the Comptroller General's office, and I think there has been general acceptance of this view informally. But we don't have any formal opinion from the Comptroller General yet. There might be a change, but I think the indications are based on our informal discussions that there is a very great likelihood that we will receive a favorable reply.

(Subsequent to the hearing the Joint Committee received a letter from the AEC forwarding the report of the Comptroller General on the proposed contract between the AEC and the Consumers Public Power District of Nebraska. The correspondence will be found on p. 64.)

Representative HOLIFIELD. Well, I am inclined to think that the legislative history shows that Congress did contemplate some long-time arrangements in these specific instances. But your opinion and my opinion, I am afraid, doesn't carry the same weight as the Comptroller General's may carry. It does put us in a rather peculiar position. You have a procedure possibly under challenge and ask us to waive the 45-day waiting period, where possibly during that

45-day waiting period, the Comptroller General, realizing the urgency of the decision of the committee, might be constrained to speed up his decision a little bit.

Mr. DIAMOND. I think this is one of the hurdles we have to overcome before we can finally enter into a contract.

Another requirement, that is the statutory requirements that we submit these arrangements to the Joint Committee, is a second condition we have to meet. We are trying to comply with these requirements concurrently.

Chairman DURHAM. Suppose he does rule that you don't have this authority?

Mr. DIAMOND. Then we will not be able to enter into the contracts.

Representative HOLIFIELD. What would be your procedure for the Commission under those circumstances?

Mr. DIAMOND. Depending upon what the opinion states, we might attempt to revise or revamp our contracts, if this is possible, or else perhaps ask for statutory authority in the next session of Congress.

Chairman DURHAM. How long has the question been before the Comptroller General?

Mr. DIAMOND. The formal submissions have been before the Comptroller General since the 12th and 13th of September. It is just a matter of days.

Chairman DURHAM. No lawyer can render a decision in that length of time.

General FIELDS. We have had it under discussion for sometime as a result of the previous submissions. I am under the impression that the Comptroller General is giving this some active consideration right at the moment.

Representative HOLIFIELD. All right, we will proceed with your statement.

Chairman DURHAM. You have the committee in rather a bad position, however. You should clear these things before you bring them up here, if you can.

Mr. DIAMOND. I don't believe the waiver by the committee would really go to the question of our authority to enter into the particular contracts. I think the waiver would be assuming the AEC has the legal authority to enter into these contracts. The Joint Committee would merely waive the 45-day waiting period.

Representative HOLIFIELD. This applies to both Consumers and Northeastern States, this pending opinion?

Mr. DIAMOND. Yes; there are two separate letters that have been submitted to the Comptroller General.

General FIELDS. Mr. Delmar M. Morris, the Division of Reactor Development's Assistant Director for Administration, has been the principal negotiator for the two arrangements now before you, and I believe that he will be able to answer any detailed questions you may have.

In a letter dated September 14, 1957 (see p. 11), to me, Mr. Ramey indicated that your committee would like a status report on the Commission's other negotiations under the power reactor demonstration program.

In the second round, as the Joint Committee already knows, the Wolverine, as well as the RCPA proposals are now in abeyance, pending further consideration by the Commission as to what action it deems

appropriate regarding the making of substitute arrangements for obtaining design-development undertakings for the reactor plants. Our letter of August 23, 1957, explained the circumstances of the Wolverine situation and we shall keep you informed of further developments on this and the RCPA undertaking.

Immediately following enactment of Public Law 162 the Commission forwarded to Piqua and Chugach a questionnaire designed to elicit more detailed information concerning their conventional operating costs. We have not as yet had responses from them in this regard, but as soon as we do, we plan to initiate negotiations as expeditiously as possible.

In the third round, the Commission is awaiting a revised proposal from the Florida group and the staff is in the process of giving detailed consideration to the proposal submitted by the Carolinas-Virginia group on August 29, 1957. No other third round proposals have as yet been received.

Mr. Ramey's letter also requested the status of the Commission's work on the gas-cooled reactor prototype, the plutonium recycle experimental reactor, and the production reactor for special nuclear materials. Mr. Vance's letter of September 13, 1957 (see p. 3), which forwarded the Consumers and Northern States request, our request for their waiver, also included a status report on these projects. I and members of my staff are prepared to answer any further questions you may have in connection with these projects.

Mr. Chairman, I have Mr. Morris here, and Mr. Roddis, the Deputy Director of the Division of Reactor Development, and Mr. Tammaro, Assistant General Manager for Research and Industrial Development. They will endeavor to answer any questions you have.

Representative HOLIFIELD. Let us take a look at the Consumers project first, as it was first in line. What are the changes that have been made since your submission to the committee?

Mr. MORRIS. There are no significant changes, Mr. Holifield. It is the same basic arrangement that we contemplated earlier.

Representative HOLIFIELD. Your postconstruction assistance, I believe you had a $2 million item and then we received a letter right toward the end of the session indicating that you wanted to raise that to $8 million.

Mr. MORRIS. Yes, sir.

Representative HOLIFIELD. We didn't have time, of course, at that time to go into that matter. I notice that this is listed as postconstruction assistance. Will you break that down and tell us what what that item is for?

Mr. MORRIS. Under this arrangement Consumers will pay all of the normal operation and maintenance costs, and receive the steam in return for paying these costs. The Commission has undertaken or will undertake to pay the costs of extraordinary maintenance, and the costs of the fuel above a certain amount.

Representative HOLIFIELD. Is that the fabrication of the fuel? You have a waiver of fuel use, $1,325,000, and so you must be talking about the fabrication and processing of fuel.

Mr. MORRIS. The Commission will pay the cost of fabricating the first core. Beyond that, consumers will pay all fuel costs up to $36.40 per kilogram of uranium fed to the reactor. The Commission will pay the excess costs above $36.40 per kilogram. The estimated amount

of this assistance in the fuel cost area and extraordinary maintenance is estimated to be $8 million over the 5-year operating period.

Representative HOLIFIELD. How much is that?

Mr. MORRIS. $8 million over the 5-year operating period.

This is exclusive of the waiver which is shown separately in our submission.

Representative HOLIFIELD. This will apply strictly to the fuel costs?

Mr. MORRIS. Yes, sir; and the extraordinary maintenance.

Representative HOLIFIELD. What would come under that? Is that additional personnel to operate the reactor?

Mr. MORRIS. This would cover the cost of replacing certain components which might fail which would be considered to be beyond the expectations of normal maintenance.

Representative HOLIFIELD. This would in effect be a subsidiary for operation.

Mr. MORRIS. It will be picking up the excess costs of extraordinary maintenance and fuel costs, and I might say that this leaves Consumers in a position where on an estimated basis they expect their operating costs to be in the same range as conventional power costs.

Representative HOLIFIELD. Then does that mean that they will receive the steam at a conventional price?

Mr. MORRIS. They will receive the steam in consideration of paying the normal operation and maintenance costs, and fuel costs up to this point where we take over. This is estimated to be in the same range as conventional prices; yes, sir.

Representative HOLIFIELD. Now, in the report on the Consumers case, we didn't provide any item there for waiver of fuel-use charge. Why was that? In the breakdown which you gave us, why was that?

Mr. MORRIS. This will be a Government-owned reactor.

Representative HOLIFIELD. So this waiver of fuel-use charge here is actually a computation of fuel-use in a Government-owned reactor?

Mr. MORRIS. Yes, and another way of looking at it would be that if we don't charge ourselves fuel-use charges, it disappears.

Representative HOLIFIELD. Do you think that is consistent with what the committee did?

Mr. MORRIS. Yes, sir; we do.

Mr. RAMEY. Was that question considered, that the committee had cut out any waiver for the Consumers project because it was a Government-owned project and now you are putting in a waiver? Is that consistent and has that been considered seriously?

Mr. MORRIS. Well, I can't say it has. But in the arrangement which contemplates that the Commission will pay all costs of fuel above $36.40 per kilogram, whether it is in or out it appears to me to be insignificant in this arrangement.

Representative HOLIFIELD. Well, it is insignificant unless it establishes an important principle. I am not commenting on it one way or the other, we are exploring the reason for you placing it in when we did not have it or we didn't feel it was necessary to put it in the cooperative arrangements where the Government owned the reactor.

Chairman DURHAM. How would that affect the request for appropriations? Do you request the item there?

Mr. MORRIS. The fuel-use waiver is not out-of-pocket cost to the AEC.

General FIELDS. It is a requirement that there be a consideration of it. It is required in the act that there be waivers, and resting 45 days before the committee. I would have to go back and search the record but I think the waiver is not in there because it is a Government-owned reactor and this is true, I believe, in the case of the second-round proposals that are there. But could we look the record over and submit this for the record?

Representative HOLIFIELD. I think we ought to clear this up.

General FIELDS. I think that we should, too.

The reason it is in here is to show comparability in the total assistance.

(The AEC subsequently informed the Joint Committee that "the waiver was a nonfund item and was not included in the appropriations.")

Representative HOLIFIELD. I think it is all right as a matter of keeping track of the amount that it is costing the Government, but as I understand it this program justification under September 13 has it down there. Is that amount carried in the contract?

Mr. MORRIS. No, sir. The amount carried in the contract is $8 million. The reason it was shown in this statement was to show completely and in comparison with previous statements the value of AEC assistance.

Representative HOLIFIELD. The waiver fuel cost charges are added to the $8 million and it is not part of the $8 million?

Mr. MORRIS. That is right. It is not part of the $8 million.

Representative HOLIFIELD. I can't see any sense in waiving the fuel-use charges, where it is the Government's own reactor. I could see it if it was private industries reactor.

Now of course we naturally haven't time to look at this contemplated contract. We only received it I think within the last day or two and part of the staff has been on vacation, and Mr. Durham and I just arrived here this morning. But I did notice in going through the program-justification data which you presented to us, on page 4, under item "H," you have in case of an invention or discovery is made by Consumers in connection with the work under the contract, the Commission will receive a nonexclusive irrevocable royalty-free license for governmental purposes. Is this some peculiar type of a patent arrangement?

The Commission is entitled to patent rights on its own research and development work, not only for governmental purposes but for release to all other private industry. I don't have the language of the patent provision before me in the contract so I am unaware as to what the exact language is. Should you submit a copy of that draft? Could we see one to look at?

Mr. MORRIS. The draft contract, you mean, sir?

Representative HOLIFIELD. Yes.

Mr. MORRIS. Yes, sir; we could.

Representative HOLIFIELD. I mean just to look at right at this moment so I can see what I am talking about on this matter.

Mr. RAMEY. Does the Commission have different patent arrangements with the equipment supplier where the Commission is putting the money in?

Mr. DIAMOND. We do. We have the right to make determinations with respect to all inventions that are conceived during the fabrication or construction of the reactor, with the equipment contractor retaining a nonexclusive royalty-free license.

Mr. RAMEY. That is a direct contract you have with North American; in that case?

Mr. DIAMOND. We do not have the contract yet, but it is contemplated it will be a direct contract.

Representative HOLIFIELD. Why do you have this in for the Consumers? Where do they obtain any patent rights?

Mr. DIAMOND. This is in connection with operation of the reactor itself. The likelihood of inventions being made during that period I think are rather small compared to inventions that might be made during the course of a fabrication or development work.

Representative HOLIFIELD. I think that is true. That is one reason why I asked the question.

Mr. MORRIS. Consumers is bearing the normal operation and maintenance costs and taking the risks of these costs.

Representative HOLIFIELD. What did you say?

Mr. MORRIS. Consumers will bear the normal operation and maintenance costs, and take some risks in that respect, which led us to give them this patent arrangement.

Representative HOLIFIELD. What risk will they take, if you are going to give them a cushion for the first 5 years over and above conventional costs of steam?

Mr. MORRIS. We are protecting them in two areas. That is the extraordinary maintenance and the fuel. The other elements of cost may vary from their estimates, and they will get no protection. Furthermore, Consumers is putting $5,220,000 into the capital cost of this reactor, which they may or may not receive return from.

Representative HOLIFIELD. Well, of course, any donation that they put in is just like any other. There have been grants or donations made by other companies. There was in the case of the Army package power reactor also. There were some grants on that, but the Government owned it.

Mr. RAMEY. Is your theory there that the Commission is not putting any money into the operation and therefore you do not take title to patent rights?

Mr. MORRIS. The Commission is putting some money in.

Mr. RAMEY. But you are still nevertheless not taking title, and you are letting them take title and you are just picking up the other part?

Mr. MORRIS. As we pointed out the research and development and construction will be under separate contracts where we will expect to get title to patentable inventions.

Representative HOLIFIELD. How do you interpret the phrase "for governmental purposes"?

Mr. MORRIS. In connection with such work as will be done.

Mr. DIAMOND. This would refer to the Commission's programmatic activities, that is, reactors that we build in connection with our own programs.

Representative HOLIFIELD. But it would not apply to granting the right to use these patents to all other participants in industry?

Mr. DIAMOND. It would not.

Representative HOLIFIELD. Do you feel justified in deliberately ruling yourself out from a sole governmental right to this patent to do as they please not only for governmental purposes, but to make known to industry itself, where you own the reactor and put in a high percentage of the money involved—where you furnish the fuel, and you fabricate the core, and you furnish an $8 million operating fund, and yet you give away the patent rights?

Mr. DIAMOND. I think this is a matter which results from negotiations. I think that there are some equities on the side of Consumers here. They are making a financial contribution to the project, and they are assuming some risks with respect to operation. Furthermore, as I pointed out earlier, the likelihood of any inventions occurring during operations is rather slim, and so I do not think that there is anything of real value that the Commission has given up.

Representative HOLIFIELD. But yet you have very carefully put in something there so that if there is anything of value, Consumers will have it.

Mr. DIAMOND. And the Government will have it for governmental purposes.

Representative HOLIFIELD. The Government will have it for use in its own reactor, but not to release to industry generally, although the majority part of the cost has been paid by the Commission.

Mr. RAMEY. Is this what you might say is a departure from normal AEC policy, where the Commission puts money into any research and development work or operation work, it has a right to pick up the title?

Mr. DIAMOND. Generally the Commission would under such circumstances retain the right to dispose of patents as it saw fit. As I say, this is the result of negotiations.

Representative HOLIFIELD. Did the Consumers require this, and would the Consumers people be interested in patent rights? They are distributors of electric current, and they are not manufacturers of equipment. Isn't this a bit odd? I ask you again, did the Consumers require this provision?

Mr. DIAMOND. May I consult with my colleagues for a moment? I am told that they did insist on this.

Representative HOLIFIELD. Now, I had a talk this morning with Mr. Schacht, and I got just exactly the opposite conclusion, and so when Mr. Schacht comes to the stand, I am going to ask him the same question—if the Consumers required this.

Mr. DIAMOND. My information may be wrong, but that is what I am told.

Representative HOLIFIELD. All right.

Mr. FIELDS. Mr. Chairman, could I return to just one point? On this waiver, I notice that the report of the committee does indicate that in our submittal we had indicated this waiver amount to the committee itself. However, in the action taken, although cognizance I presume was taken, because here if the second round reactors were Government-owned, it was not necessary to grant waivers. I should not say "grant" but for the committee in its authorization to take cognizance of this. But I wish the record to show that we did submit this same amount, $1,325,000, to your authorization committee and cognizance was taken of that fact in the report.

Mr. RAMEY. But the total authorization did not include this amount, though, did it?

Mr. FIELDS. In your total authorization, you authorized $20 million, as I recall, for the third round. There was no other authorization of waivers other than those that were listed. You did not have to authorize other waivers at that time.

Representative HOLIFIELD. There would not be any money in there then, on that basis, would there?

Mr. FIELDS. There is no money in here for the second round, either, but you take cognizance of that in your report, since it is a government-owned reactor, and it seems to me that has taken care of the necessities of the law.

Representative HOLIFIELD. In terms of money, in other words, they authorize this amount of money, but not in the authorizing of it as a basis for an actual waiver of use materials. That may be the way the committee operated.

Mr. FIELDS. Well, that is a different construction than we have put on it. It seems to me at the moment here that we have construed—that it would be, since it is a Government-owned reactor, a part of total cost of the project. It would be allowable.

Mr. RAMEY. But the law as you have indicated merely authorizes $20 million, and I think the legislative history was pretty clear that that was intended for the third round.

Mr. FIELDS. That is right.

Mr. RAMEY. So then how can you have a waiver for the first round?

Mr. FIELDS. How can we have a waiver for the second round, I ask you, too, because we asked for it.

Mr. RAMEY. And you could not have it for the second round, either.

Mr. FIELDS. I presume the record shows that the Joint Committee was cognizant of this and felt because they were Government-owned reactors that waiver action was not necessary in the authorization bill itself. I think you have to proceed on that basis.

Mr. RAMEY. I think that there—and again it is subject to review here—there might be a contrary interpretation that since they were Government-owned reactors there was no waiver necessary.

Mr. FIELDS. That is the interpretation we have put on it, but we are indicating it here as a part of the whole package.

Representative HOLIFIELD. I notice in your cooperative presentations that you did not present them on the basis of a waiver of fuel. You presented it on the basis of a fuel inventory; is that right?

Mr. FIELDS. The budget proposals had indicated the amounts of materials, as I recall, in them but I think that our submittals also did have an estimate of what would be involved in the use charges with respect to materials that would be in the inventory or in the reactor in the course of this.

Mr. DIAMOND. I might point out that the contract itself is silent with respect to the waiver of use charges. This is consistent with the idea that there is no waiver of use charges as such.

Representative HOLIFIELD. I have no objection to it as a bookkeeping item. I think that we should know what it is. However, I think that I take the same position Mr. Ramey takes; that the $20 million authorization was for the third round. We took the position that the cooperative arrangements were Government owned and therefore there

was no need from an authorization standpoint for you to have an authorization to use fuel in the Government's own reactors. I think that that ought to be pretty clearly understood. I just can't see the implication. I don't know what it would be of setting a precedent for doing that at the present moment.

Mr. FIELDS. I think it should be cleared up also.

Representative HOLIFIELD. Perhaps it is all right, but I think as a principle the Government should not have to consider paying itself for its own fuel in its own reactors.

Mr. DIAMOND. I do not believe there is any difference between the Commission's and your views, and Mr. Ramey's views. I think that we acted along those lines in writing the contract, because there is no reference at all to the waiver of use charges.

Mr. RAMEY. Then possibly this submittal might be amended, that the waiver of use charge is not part of it, then, because it is a variance, it seems to me, from what our understanding was.

Mr. DIAMOND. I believe this change could be made to show it is more a matter of bookkeeping, rather than any formal waiver of use charges.

Representative HOLIFIELD. Are there any other changes? We have not had a chance yet to study this, and we are going to hold in abeyance our decision until we do have a chance to study it, but can you call our attention at this time to any other change in the consumers contract?

Mr. MORRIS. You are referring, I think, to these factors.

Representative HOLIFIELD. The Government is entitled to the plutonium, per se.

Mr. MORRIS. That is right, and I can think of no other significent changes as compared to the arrangement described to you in earlier hearings.

Representative HOLIFIELD. Are there any further questions on that? Are there any questions from members of the staff on the Consumers case? If not, let us pass on to the next question, the Northern States project.

This is the first time that we have had this before the subcommittee, because it was not in condition to be put before us before. So I think that we might give the specifics of this arrangement, Mr. Morris.

Mr. MORRIS. The Northern States Power Co. has undertaken to build a boiling water type reactor plant of 66,000 kilowatts capacity at an estimated cost for development, fabrication, and construction of some $21,600,000. They have requested assistance from AEC in the preconstruction and development period and for preconstruction research and development work of $5,500,000, and for $500,000 of research and development work during the postconstruction period, and for waiver of fuel use charge up to a ceiling of $1 million, for a total amount of AEC assistance of $7 million.

Northern States Power Co. contemplates that the design, research, development, and construction will be performed by the Allis-Chalmers Co.

Representative HOLIFIELD. What do the initials CUAPA refer to?

Mr. MORRIS. That is Central Utilities Atomic Power Associates. That is a group of 10 utilities neighboring there who are furnishing $3,650,000 to this project in return for certain information and experi-

ence. There will be no contractual relationship between the AEC and the Central Utilities Atomic Power Associates, but a portion of the financing for the Northern States undertaking will be obtained from this group of utilities.

Representative HOLIFIELD. That is $200,000, is it?

Mr. MORRIS. The amount of financing provided by these 10 neighboring utilities is $3,650,000. That is shown on page 8 of our submission.

Representative HOLIFIELD. What is the total contribution in this of the AEC?

Mr. MORRIS. Seven million dollars, including waiver of fuel use charge in the amount of $1 million. The remainder of the AEC financial assistance is entirely for research and development work.

Representative HOLIFIELD. What is the postconstruction research and development of $1,700,000? Is that furnished by the AEC?

Mr. MORRIS. $500,000 of that would be furnished by AEC for specific research and development work to be specifically defined in the contract.

Chairman DURHAM. Why do you limit the operations to 5 years?

Mr. MORRIS. This is the duration of our contract period. Northern States will continue to operate it indefinitely, and our feeling is that we will obtain the information we are seeking within this 5-year period.

Representative HOLIFIELD. Will you please describe the postconstruction research and development? You mentioned $500,000 of the $1,700,000 and what about the other $1,200,000?

Mr. MORRIS. The $1,200,000 is then to be provided by Northern States, and this has not been defined.

Representative HOLIFIELD. That is not an AEC contribution?

Mr. MORRIS. No, AEC's assistance is $500,000. As I say, this is to be defined in the definitive contract as specific research and development work.

Representative HOLIFIELD. Well, now, is that consistent with the committee report which on page 20 and paragraph No. 3 states:

> Provision is made in the third round for postconstruction research and development assistance which if attempted to be applied as proposed in the second round which involves only Government-owned reactors, could result in outright subsidies to the operators of private reactors. The committee does not approve the obligation of funds by the AEC for private research and development contracts which are in effect a subsidy for operational costs of private licensees. Such a proposal would raise grave questions as to violation of section 169. Information and data accumulated as a result of postconstruction operations should be available to the AEC as part of a privately owned reactor's obligation for preoperation assistance from the AEC. The committee recognizes that AEC may contract for special services from any private reactor owner on the basis of commercial services rendered.

Leaving out that last sentence that I read there, which the committee recognizes as an area, do you consider that your $1,200,000?

Mr. MORRIS. That is Northern States $1,200,000.

Representative HOLIFIELD. I am talking about $500,000.

Mr. MORRIS. That will in no way be used to defray operating costs. We do not yet have a definitive contract with Northern States, but it is the intention of both parties to specifically define research and development work that will be outside of any consideration of paying operating costs.

Representative HOLIFIELD. In other words, the information that you get as a result of the operation of the reactor would come to you gratis.

Mr. FIELDS. As a part of the contract, yes, sir.

Representative HOLIFIELD. But if there was some specific work you wanted done, outside of the ordinary operations, why, this amount would not apply to that?

Mr. FIELDS. That is right.

Representative HOLIFIELD. So that would come within the meaning of the last sentence in that paragraph.

Mr. FIELDS. This could be special work on looking at the fuel element, and how they behaved and experimentation with respect to those that had been in it for some time. That would be rather just the routine of the processing and recovery of the material in them. It is looking at things that you would not ordinarily do. Once you get in a power operation, they would not be a part of the operating cost. But this is special things, what went wrong with this, and why did it fail at 2,000 hours, instead of 3,000 hours.

Representative HOLIFIELD. The committee has no objection to that type of thing.

Mr. FIELDS. It is that type of thing in the third round.

Representative HOLIFIELD. And clear-cut contracts. We do not want it to be used as a subterfuge for possible construction operation, of course, which is not in accord with the committee's ideas.

Mr. FIELDS. We understand that; yes, sir.

Mr. RAMEY. On that postconstruction research and development, would you pick up the patents like you would on your other construction?

Mr. MORRIS. All patent rights for research and development work paid for by the Commission will reside in the AEC.

Representative HOLIFIELD. That applies to preconstruction as well as postconstruction?

Mr. MORRIS. Yes, sir. I would like to call to your attention a mistake in arithmetic on page 7 of our submission.

Representative HOLIFIELD. All right.

Mr. MORRIS. Where the total is $21,600,000, in the first column. It should be $27,100,000.

Representative HOLIFIELD. Is this contract consistent with the Yankee Atomic Power contract?

Mr. MORRIS. Very similar to it.

Representative HOLIFIELD. There is no basic difference, is there?

Mr. MORRIS. There is no basic difference.

Mr. FIELDS. As I recall in the other two, there is no postconstruction research and development assistance.

Mr. MORRIS. That is right; yes.

Mr. RAMEY. In terms of your rights to information, the GAO's access?

Mr. MORRIS. That has been taken into consideration here, and such rights will be fully spelled out. I might point out that in this case the AEC is contracting directly with Northern States Power, and it will be a direct two-party arrangement, and it will not be contracting with a group or a newly organized company.

Representative HOLIFIELD. The Northern States, that is one corporation, is it?

Mr. MORRIS. That is right.

Representative HOLIFIELD. Has there been any difference in the corporate setup of the Northern States since the original submission to the committee of their proposal.

Mr. MORRIS. No, sir.

Mr. FIELDS. This proposal, as I understand it, is conformed to our third-round invitations, from the very beginning, and there have been no changes in it.

Representative HOLIFIELD. This group that is contributing toward it, that is a separate contract between the CUAPA and the Northern States?

Mr. FIELDS. Yes, sir; and there is no contractual relationship between the AEC and this group.

Mr. RAMEY. Is it consistent with your other financial data and information that was submitted during the authorization hearings on Northern States?

Mr. MORRIS. Yes; nothing has changed.

Mr. RAMEY. Is your patent arrangement similar to Yankee and PRDC?

Mr. MORRIS. Yes; that is the patent rights with respect to the work AEC is paying for will reside in AEC, and the other party will receive a nonexclusive license with respect to the work they are paying for, and it would be just the reverse.

Mr. RAMEY. That is to say, they take title and the AEC——

Mr. MORRIS. With respect to the work they are paying for; yes, sir.

Representative HOLIFIELD. Has the presentation of this arrangement with the Northern States people in Minnesota had any effect upon your consideration of the Elk River Cooperative group? Is your situation in getting this the basis of disqualifying the other people in any way?

Mr. FIELDS. In my mind, it is completely independent.

Representative HOLIFIELD. It is completely independent?

Mr. FIELDS. Yes, sir.

Representative HOLIFIELD. And the Commission is still of the opinion that the type of reactor proposed by the Elk River people, which they plan to build, is still desirable?

Mr. FIELDS. It was our opinion as of yesterday. It was desirable on that basis as it was submitted, and if we had that same basis today, I would say it would be desirable; yes, sir. With this increase in costs that has come into the picture, I do think that we need time to reconsider it, and see what our opinion is on that, sir.

Representative HOLIFIELD. Unless there are further questions on that, the committee will excuse the Commission witnesses at this time, and ask them to stand by, while we call to the witness table these other witnesses. First we will give the courtesy of the witness table to Mr. William J. Connell, Senator Humphrey's representative.

I understand you have a statement to make on the Elk River matter.

STATEMENT OF WILLIAM CONNELL, ASSISTANT TO HON. HUBERT H. HUMPHREY, A UNITED STATES SENATOR FROM THE STATE OF MINNESOTA

Mr. CONNELL. Thank you very much, Mr. Chairman, and members of the committee. As soon as we were notified by the committee staff this morning that the Atomic Energy Commission would not present the Elk River proposal before the committee today——

Representative HOLIFIELD. Will you pause just a moment and give your full name and your official position?

Mr. CONNELL. I am William Connell. I am assistant to Senator Hubert H. Humphrey.

As soon as we were notified by the committee that the Commission would not present the RCPA proposal at this meeting, I was in touch with Senator Humphrey, who was out of the city, and he instructed me to check with the Atomic Energy Commission and with the RCPA people to determine just what the story was. The information we received from the Atomic Energy Commission was rather vague. There was some indication that perhaps the whole project was completely on the skids. Therefore, I know that Senator Humphrey will be very gratified to hear from the Atomic Energy Commission that the matter is still very much under consideration, and that there may be a possibility of working out something.

I had merely wanted to bring to the Joint Committee the Senator's deep interest in this project, and to ask certain questions of the Commission which I believe have now been answered.

Representative HOLIFIELD. We are aware, of course, of Senator Humphrey's deep interest in this matter. He has conferred with members of the committee, and also with the staff on many occasions, as has his office. Of course, this comes as a surprise to the committee, as well as apparently to the Commission.

Mr. CONNELL. It comes as a surprise to everybody, and in fact, the Elk River people did not know about it this morning until we called them.

Representative HOLIFIELD. Is that so?

Mr. CONNELL. Yes, sir.

Representative HOLIFIELD. That is an amazing statement that their supplier did not inform them, as people they were working with on this matter. It appears to the chairman of the subcommittee that this is a very abrupt decision on the part of the American Machine & Foundry people. I hardly think the records will be clear unless we get a statement from them as to what has caused this abrupt withdrawal of their proffer to build this reactor.

Mr. CONNELL. Yes, sir. I tried to get in touch with the president, who is in town, I understand. He is in town today, but I could not reach him before the 1:30 meeting today. It might still be possible to reach him.

Chairman DURHAM. What kind of a contract did the Elk River people have with the American Machine & Foundry Co.?

Mr. CONNELL. It was a contract for the construction of the reactor and the superheater in the amount of approximately $5,868,000.

Chairman DURHAM. Was it a fixed-price contract?

Mr. CONNELL. It was a cost-plus contract with a ceiling I believe of $5,868,000.

Representative HOLIFIELD. The committee sent a telegram under date of September 14 to several people that are interested in this matter, and among those was Mr. A. V. Peterson, vice president of the American Machine & Foundry, and invited him to appear here today. At this time the Chair would like to inquire if Mr. Peterson is present in the audience, or if any other representative of the American Machine & Foundry Co. is present?

The Chair observes that no one rises, and so it is assumed that no representative of the American Machine & Foundry Co. is present, although the Chair is informed informally that there was a representative present here at the beginning of the meeting.

The Chair is also informed that a member of the staff recognized the American Machine & Foundry Co. representative in the audience and asked him if he wanted to testify today, and apparently he did not. The Chair, if he had known he was present, would personally have advised him to testify.

Did you have anything further to say?

Mr. CONNELL. No; except to correct the record. I believe it was Senator Humphrey who said on the floor that it was his understanding that this contract was ready to be signed, on the desk of the Chairman of the Atomic Energy Commission, and it could be signed in a matter of weeks. I believe that was the story up until yesterday. He will be glad to know that the Atomic Energy Commission apparently was ready to sign this contract.

Thank you.

Representative HOLIFIELD. Thank you, Mr. Connell.

Mr. Robert Forsythe, administrative assistant to Senator Thye, is present. Mr. Forsythe, would you like to make a statement on behalf of Senator Thye?

STATEMENT OF ROBERT A. FORSYTHE, ADMINISTRATIVE ASSISTANT TO HON. EDWARD J. THYE, A UNITED STATES SENATOR FROM THE STATE OF MINNESOTA

Mr. FORSYTHE. My name is Robert A. Forsythe, administrative assistant to Senator Thye of Minnesota.

Mr. Chairman, I just want the record to show that Senator Thye wished to be represented at this hearing today, and to assure the committee that on this particular occasion the contract involving Elk River, the feeling of the two Senators of Minnesota were most similar, and I can assure you that both were shocked this morning when we heard at 9:30 or 10 o'clock that A. M. & F. was withdrawing temporarily from this contract.

The Senator's surprise can be indicated best by reference to the letter which you received in your files this morning in which he again brought to the committee's attention the fact that this contract had been under negotiation for many months and was ready for final negotiation and signature by all parties concerned. We trust and hope that in the interim period, between this meeting and the next meeting of the committee, negotiation will take place which will allow this very important project in Minnesota to go forward. That is all I wish to say.

Representative HOLIFIELD. Thank you, Mr. Forsythe.

The committee received a telegram under date of September 16 from O. N. Gravgaard, president of RCPA, which reads as follows:

ELK RIVER, MINN., *September 16, 1957.*

JAMES T. RAMEY,
Capitol Building,
Washington, D. C.:

Appreciate committee invitation to appear and wish to compliment the committee on their strong interest in respect legislation and activities expedition this fine program. In view of our having reached complete agreement on major points with the AEC and their agreement to request waiver of the 45 days it appears that all matters of this interest between our cooperative and the AEC have been settled. We therefore see no advantage in taking up the committee's time further and duplicating what the AEC will present. Further delays will seriously handicap the cooperative supply position and the manufacturer cost problem. The Joint Committee's interest in expediting conclusion of all these arrangements is sincerely appreciated and our association urges in these interests that the committee can find a basis for waiving the 45-day period.

Sincerely,

O. N. GRAVGAARD, *President, RCPA.*

Representative HOLIFIELD. That is the Elk River Association. That was evidently before he received the news.

Mr. Kenneth M. Olds, attorney from Wayne, Nebr., representing the Nebraska Generating & Transmission Cooperative. Mr. Olds, are you present, sir? Would you like to make a statement?

STATEMENT OF KENNETH M. OLDS, ATTORNEY, REPRESENTING THE NEBRASKA GENERATING & TRANSMISSION COOPERATIVE, WAYNE, NEBR.

Mr. OLDS. Yes, sir. I would. My name is Kenneth M. Olds, attorney of Wayne, Nebr. I am representing the Nebraska Generating & Transmission Cooperative, which is an organization of 22 rural public-power districts in the State of Nebraska. The public-power districts are what we commonly call the REA's, and they serve approximately 50,000 rural consumers in Nebraska. We are appearing here in connection with the proposal of Consumers Public Power District.

We want to make it clear that we are not opposing the construction of an atomic plant in Nebraska, and we also want to make it clear that our organization has no plan or proposal to construct a plant of its own. We are only raising the question that we feel we should have an opportunity to review and consider the proposal that has been submitted by Consumers, together with the AEC.

We in Nebraska first learned of this hearing, I believe Saturday, in the newspapers in Nebraska, and we immediately took steps to send a telegram, and copies of which I have here available to the committee, and I would like to leave with the committee. I have extra copies, and I believe the chairman perhaps has the original of that telegram.

Representative HOLIFIELD. The Chair has the original and it will be placed in the record at this point.

(The following telegram was sent to the Subcommittee on Legislation of the Joint Committee on Atomic Energy by the Nebraska Generating & Transmission Cooperative on September 15, 1957:)

LINCOLN, NEBR., *September 15, 1957.*

Re hearing on contract between Atomic Energy Commission and Consumers Public Power District.

Our first notice of your Tuesday hearing was carried in the press yesterday.

We respectfully ask permission to intervene and be heard after studying the contract. It was not until 2 days ago that we learned through the news services that a contract had been negotiated.

Representing 22 rural electric districts in Nebraska, we urgently request an opportunity to study the Consumers District contract with AEC before it is approved by Congress. We have had no chance to see this contract. Rural electric users in Nebraska object to secrecy and haste. The 45-day waiting period was intended by Congress to safeguard the public interest.

We support an atomic-fueled powerplant for Nebraska provided it does not adversely affect our customers.

We must be assured that the construction of the proposed plant is timed and coordinated into the State power program and that our users, including irrigators, are not deprived of their fair share of low-cost power.

A. G. SYDON,
President, Nebraska Generating & Transmission Cooperative.

Mr. OLDS. I am informed that the proposal was submitted to the committee or the subcommittee approximately on Friday. We arrived here yesterday by plane and obviously we have had no opportunity to examine the proposal of Consumers, although it was made available to us at about 11:45 this morning.

Since the copies of the telegram have been made available, perhaps it is not necessary to take the time at this time to read it, but we do want to emphasize the fact that we have no objection whatsoever specifically to the proposal, but we have had no opportunity to examine the proposal or apparently a draft of the contract that has been presented. We feel that it may affect the rural or REA's in Nebraska. We have an unusual situation in Nebraska in that we have a public-power State with the systems integrated so that at the present time the REA's and Consumers Power District purchase all of their power from one agency, or I should say substantially all of their power from the Nebraska public-power system.

In view of that fact, the proposal here to construct this plant may have a very definite effect on the operations of the REA's in Nebraska.

For the information of this subcommittee REA has loaned approximately $100 million to the REA's of Nebraska. In addition to that, REA and GSA have advanced another $45 million to the organizations that provide the generation and transmission lines of the Nebraska public-power system, which is, in turn, carrying the power to the rurals.

Chairman DURHAM. You generate your own power?

Mr. OLDS. No; we buy it from the Nebraska public-power system. It is just as Consumers does substantially all of its power at the present time.

Representative HOLIFIELD. Total Federal investment there is how much in the distribution system?

Mr. OLDS. In the rural distribution system, about $100 million. But there is an additional $45 million which REA and the GSA have advanced to the Nebraska public-power system or other public agencies to provide generation facilities.

Representative HOLIFIELD. In other words, the Nebraska public power; I understand there are three groups there in Nebraska, the State-chartered groups?

Mr. OLDS. They are all public-power districts.

Representative HOLIFIELD. There are three public-power districts? Now, are you saying that they have borrowed $45 million from the Government?

Mr. OLDS. That is right, sir.

Representative HOLIFIELD. And yet they have bond-issue power; do they not?

Mr. OLDS. They have those in addition to the loans from the Government, Mr. Chairman.

Chairman DURHAM. Why would this affect you? Because you would expect to get this, or are you satisfied with your present contractual system with Consumers Public Power?

Mr. OLDS. It would affect us in this way, in that the rurals have recently entered into a 35-year contract to buy their power from the Nebraska public-power system. Up to the present time, Consumers has also been purchasing its power there. We have what amounts to a cost contract to purchase our power, and, obviously, if there is the construction of a conventional plant or, I should say, a conventional part of this plant, together with the atomic plant, it will have an effect on our future operations.

Chairman DURHAM. How would that be? You have your 35-year contract, and, if this power is integrated into the Consumers system, your contract would still be valid.

Mr. OLDS. Well, sir, for one thing, we have no assurance that it will be integrated, and we have no information on that.

Chairman DURHAM. They have to integrate it into the system if they are going to use it.

Mr. OLDS. That is one of the problems that we want to be satisfied on. All that we are asking, and we are not objecting to the form of the contract, and we have not had an opportunity to examine it, but all we are asking is that the committee give us 45 days in which to do that. We are not asking for a period of time that Congress is in session, but 45 calendar days, we feel, will give us an opportunity to consult with our engineers and see what effect, if any, it would have on our operations. We have a huge investment, and the Government has a big investment in Nebraska, and we want to know where we are going in the future to repay those funds.

Chairman DURHAM. Well, I do not understand how it could be otherwise, if you have a 35-year contract, and I imagine it is on a sliding-scale cost, I do not see how this would affect you. The power will have to be integrated into that system. Otherwise, it will not be any good to them.

Representative HOLIFIELD. Your thought is, if this power is expensive power, and if it is offered for sale to you on the cost basis, notwithstanding your 35-year contract, you will have to buy expensive power.

Mr. OLDS. That is right. That is one of the problems that we are certainly confronted with.

Another problem that we have that is unique in Nebraska is that we have a great amount of irrigation. There is a summer peak of

need for electric energy during those summer months. A generating plant which is constructed to provide a year-round capacity can be very expensive. What we need is Bureau of Reclamation power during those summer months to meet our irrigation needs.

Representative HOLIFIELD. What you are asking for, then, is that the committee do not waive the 45-day period but give you that time to study the contract, and to ascertain whether this will mean an increase in costs to the cooperatives of Nebraska, who have a total of $145 million of Federal funds.

Mr. OLDS. That is exactly it, sir.

Representative HOLIFIELD. That is your request.

Mr. OLDS. That is all that we are requesting; that period of time.

Chairman DURHAM. How are you going to get an answer, because they cannot determine what the power is going to cost them? At the present time you could not determine it in 12 months.

Mr. OLDS. At least we will know what their proposal is, and what type of plant is to be constructed, and our engineers can at least give us some better advice than we as lawyers or members of the REA's can see at the present time.

Representative HOLIFIELD. Of course, this is, to a certain extent, a gamble. Any atomic-energy electrical plant is a speculation into the future, because we are exploring unknown fields. Now, if this power is integrated into the complete system, I suppose you would be willing to bear your proportional share of it. The thing that you worry about, you might be apprehensive that there might be a bloc of high-cost power allocated to the rural co-ops, and on your cost contract, and thereby put you in the position of having to pay more for your power because of that particular bloc.

Mr. OLDS. That is part of it, sir.

Representative HOLIFIELD. If it is high-priced power, and the chances are that it would be higher priced than conventional power in some way, either the Government will have to stand it or it will be a mutual burden for the Consumers and the AEC. If the integration of a higher potential cost was made into the full system, you would not mind sharing your proportional costs, would you?

Mr. OLDS. Well, I assume that if it is integrated we would have to, but, of course, there is information that has come to us, and I don't believe it is in the proposal, although I have looked at it just hastily, that perhaps a conventional part of this plant will be constructed immediately.

Chairman DURHAM. How much does your group consume of kilowatt-hours?

Mr. OLDS. I am not an engineer, and I could ask our consulting engineer to give you that information, if you would desire it.

Chairman DURHAM. I was thinking this is only a 75,000-kilowatt plant. It is not a big bloc of power.

Mr. OLDS. Mr. McKinney, the consulting engineer, is here, if you would like to have him testify.

Chairman DURHAM. If they integrated the whole thing into your system, I imagine, with $145 million of investment, you must have a lot of power.

Mr. OLDS. We do, sir.

Chairman DURHAM. Is Mr. Chantry with your same group? Do you care to make any further statement on this matter?

Mr. CHANTRY. I think Mr. Olds has covered our point very well.

Representative HOLIFIELD. Mr. Vance E. Leininger, attorney, representing the Loup River Public Power District, Columbus, Nebr., and Platte Valley Public Power and Irrigation District, North Platte, Nebr. Mr. Leininger, do you have a statement you would like to make to the committee?

STATEMENT OF VANCE E. LEININGER, ATTORNEY, REPRESENTING THE LOUP RIVER PUBLIC POWER DISTRICT, COLUMBUS, NEBR., AND PLATTE RIVER VALLEY PUBLIC POWER AND IRRIGATION DISTRICT, NORTH PLATTE, NEBR.

Mr. LEININGER. I do. My name is Vance E. Leininger, of Columbus, Nebr., and I am an attorney representing the Loup River Public Power District of Columbus, Nebr., and Platte Valley Public Power and Irrigation District of North Platte, Nebr., both publicly owned and political subdivisions of the State, and joint operators of the Nebraska Public Power system.

I have had no opportunity to prepare any written statement, but the following telegram was sent to the secretary of this committee, and I believe dispatched late yesterday afternoon. Again we have had no opportunity to have sufficient copies of it prepared. With the leave of the chairman, I would like to read it into the record at this time.

As joint owners and operators of Nebraska Public Power System, Nebraska's principal publicly owned electric generation and transmission agency we are deeply concerned with the outcome of current contract negotiations between AEC and Consumers Public Power District, and proposed large investments contemplated by Federal Government in Nebraska, as reported in the press.

We are not opposed to construction of atomic fueled powerplant in Nebraska, provided we can be assured that our investments as well as those of the Federal Government in existing generation, transmission, and distribution facilities are not jeopardized. NPPS presently supplies substantially all of consumers district's power requirements, in addition to 27 REA financed rural districts, 2 Government agencies and several municipalities with a combined peak load of over 400,000 kilowatts. Investment in generation and transmission facilities alone exceeds $90 million. Plans are underway to construct additional facilities to bring in Nebraska's share of new allotment of Missouri Basin hydro power pursuant to recent announcement by Bureau of Reclamation. Essential that proposed atomic plant be properly integrated into existing high voltage system in accordance with long standing plans and practice of public power agencies in Nebraska, and that installation of new units be properly timed so as to avoid duplicating and idling existing facilities and insure full utilization of low cost source of power.

The above information was wired to the Atomic Energy Commission last week, along with request for opportunity to review contract before negotiations were consummated which to date has not been acknowledged or granted. Additional data received since wiring Commission emphasizes importance of compliance with above request. Press reports Saturday indicated contract has been forwarded to your committee and hearing may be held Tuesday p. m. We respectfully ask permission to intervene and be heard if we deem it advisable after receiving copy of contract and opportunity to review same.

Signed:

Lloyd Kain, president, Platte Valley Public Power and Irrigation District, North Platte, Nebr., and Zack Howell, president, Loup River Public Power District, Columbus, Nebr.

I believe the committee or the staff has the original of that telegram.

Chairman DURHAM. Why would this affect you in any way? How would it affect you?

Mr. LEININGER. I cannot answer that question because this is the first time that we have seen the document. I cannot say it will affect us. I say this is the first time, but we received it at the same time Mr. Olds did, about 11:30 or 11:45, or something like that. I cannot say it will affect us, or that it won't affect us. We merely feel as though we should have an opportunity to review it and see whether it will or not. I can appreciate that the members of the committee might feel there has been some delay in indicating the interest of the Nebraska Public Power System and I can only explain that by saying that I think it was the attitude of our people that the negotiations between Consumers District and AEC were more properly and more efficiently carried on by them directly without intervention or interference of any other agencies. They have been protracted and necessarily complicated, I presume, and further complications during the formative stage certainly would not have been helpful to the project. I believe they felt that until something had been sufficiently finalized so that it could be looked at and evaluated on paper, that their position was not to interfere or try to take part or participate in those negotiations.

Chairman DURHAM. Does your group generate all of the power that you use or do you buy it from some other source?

Mr. LEININGER. We purchase some power from the Bureau of Reclamation. That is the Missouri Basin projects. The balance of it I can say is substantially all generated. There are occasional seasonal or emergency purchases from neighboring utilities. The group that I represent serves from the generational and high voltage transmission standpoint the eastern two-thirds of Nebraska, except for the area surrounding Omaha.

Chairman DURHAM. Do you serve rural electrification people?

Mr. LEININGER. We serve the group that Mr. Olds represents, as well as Consumers District, and some municipalities.

Now, as I say, we still do not know whether our clients will feel it advisable to participate any further in this procedure. This request is merely for an opportunity to review the proposals sufficiently prior to the committee taking action on it.

Chairman DURHAM. Has your group ever considered a proposal for the AEC, for a reactor?

Mr. LEININGER. No, sir. We have no interest in constructing an atomic plant at the present time; I would like to emphasize that. We are wholeheartedly in support of the enterprise of Consumers District, and we feel they are to be commended for it.

Chairman DURHAM. It looked like your interest would be served on the contract that you have with the Consumers, and not with the contract between AEC and Consumers. I do not get the point of that.

Mr. LEININGER. That is entirely possible and that may be the conclusion after we have had an opportunity to look at this one. But we recognize, of course, that this is a contract with an arm of the Federal Government, and it may have some limitations, and some qualifications in it which will govern the scheduling of developments and methods of operating the plant and other things which vitally affect costs in the unique situation that we have there with our irriga-

tion situation, which requires large blocs of power for only a short period of time, and we are concerned vitally with every new power supply in the area because of the scheduling difficulties and the problems that come about in working it into the overall picture to the best advantage of everyone.

I merely suggest that there was a waiting period set up by Congress, and it is our understanding of this legislation that that called for 45 congressional days, which I assume could not elapse until the next session is underway. Now, our clients are not asking for 45 congressional days.

Chairman DURHAM. It is a very simple contract, and you could make up your mind on that very quickly if you read it.

Mr. LEININGER. That may be, and we may conclude that. In view of the 45-day provision in the legislation, we think that a period of 45 calendar days might not be out of line. I am advised by our consulting engineer that that would in all probability be sufficient tc evaluate it and to determine how it would operate under varying conditions and see what the results are in our Nebraska picture.

We think that the Federal Government generally has an interest in this beyond the consideration of a single isolated atomic reactor plant. We think that the fact that NPPS is a substantial borrower from Federal agencies, and that the customers which it serves are substantial borrowers of Federal agencies, lends a general interest from the Federal point of view to the entire picture which justifies this opportunity to review the proposal and see whether we feel we should participate further in that or not.

I certainly want to express the sincere appreciation of myself and our group for the courtesy shown us on the part of the committee and its staff.

Representative HOLIFIELD. Thank you, Mr. Leininger.

Now we have another name, Robert L. McKinney, consulting engineer, that is with you people. Unless he has a statement to make, I will pass over him.

Mr. MCKINNEY. I have no statement.

Representative HOLIFIELD. At this time, I think that we should let Mr. Schacht of the Consumers come to the table and explain their desire on this waiver. Mr. Jones and Mr. Wilson accompany Mr. Schacht. You gentlemen represent the Consumers Public Power of Nebraska?

STATEMENT OF R. L. SCHACHT, GENERAL MANAGER, CONSUMERS PUBLIC POWER DISTRICT

Mr. SCHACHT. I have prepared, Mr. Chairman, a statement which I will read from, and there will be some additional comments, but if you would like to have this perhaps it might be helpful to you.

My name is Ray L. Schacht, general manager of Consumers Public Power District, Nebraska. I and my associates, Dr. Emerson Jones and R. D. Wilson, our general counsel, came to Washington yesterday to complete a few remaining language details on the contract between Consumers Public Power District and the Atomic Energy Commission, and to be available to this committee if they desired any information from Consumers on their project. We did not know

until arriving here that representations had been made to the committee for a further delay in completing the contractual arrangements between Consumers and AEC.

I regret that what is purely a local Nebraska matter has been injected into the Nebraska atomic-power program before this committee, and at literally the 11th hour and 59th minute.

Consumers has proceeded for the past 2 years with these atomic-power negotiations on the assurance of cooperation we received in September 1955, from the Loup and Platte districts, and which has never been disclaimed by them. I have copies of that assurance and would like to file one with the committee. That is a letter that was written to us. We inquired as to this when we first entered into these negotiations. We inquired as to whether we would have their cooperation because we felt it was impossible to proceed unless the parties were of the same mind that atomic power in Nebraska was a project we should all work for.

On September 28, 1955, a letter was addressed to Earl Mead, president of the Consumers Public Power District, Columbus—Subject: Atomic Energy Plant.

DEAR MR. MEAD: Your letter of September 16 has been received. You inquire whether there will be cooperation from other public-power agencies in connection with your proposal to build an atomic powerplant.

May we hasten to state that months ago our boards thoroughly discussed the possibility of such a plant being constructed in Nebraska. It has always been, and still is, their desire to cooperate with any public-power agency that can bring such a project to our State.

We know that you share our pride in the fact that we are supplying electricity to the people of Nebraska at a lower rate than is available in any adjoining State. It is our hope that all of us can work together to continue for the benefit of Nebraska citizens this enviable record of accomplishment in the field of electric power.

We congratulate you on your aggressive efforts to obtain an atomic plant.

We shall be happy to participate in this program by making the benefits of atomic power available through our grid system to all of the people in the State.

Very truly yours,

P. N. MCKINLEY,
President, Platte Valley Public Power and Irrigation District.
ZACK B. HOWELL,
President, Loup River Public Power District.

Neither the Loup nor Platte districts nor the Nebraska Generating and Transmission Co-op, who have filed protests on Consumers' proposal, are in any way parties to the contract between Consumers and AEC, nor is the issue of whether or not Consumers shall build a powerplant dependent upon the outcome of the atomic-power negotiations. Almost a year ago Consumers made the decision to proceed with construction of the Hallam plant, purchasing the turbogenerator in March 1957, and the boiler in May 1957. Wide publicity was given to this program, and there was general agreement among responsible engineers for all of these power districts that the added capacity was necessary to be in operation by the spring of 1960 to insure adequate capacity for the loads in the area. Actually the capacity of the atomic powerplant is only equal to approximately 1 year's load growth for the eastern two-thirds of the State. That does not mean only Consumers' load, but the rurals served by the hydrodistricts there, and the Omaha district. As late as last week the Loup and Platte districts reaffirmed the need of this capacity in their purported telegram to the AEC. That was the Hallam plant.

I might add at that point that the Consumers district has no contract to either buy or sell power to the rural group represented by Mr. Olds or are none contemplated. We do wheel power for them over some of our transmission lines, and they wheel some power for us, but we have no arrangements for buying or selling, and do not contemplate any.

In purchasing the turbogenerator and boiler, Consumers secured the maximum delay possible for specifying the steam conditions, and still obtaining delivery in time to insure the completion of construction and start of operation with conventional fuels by 1960. The time delay for specifying the steam conditions was for the purpose of securing additional time to bring our atomic-power negotiations to a close, one way or the other. If the negotiations were successfully completed, the equipment would be built for the temperatures and pressures contemplated by the reactor system, but if unsuccessful, higher pressure and temperature equipment would be secured so as to obtain greater efficiency in the use of conventional fuels.

The only open issue is whether this powerplant, for which approximately $8 million of equipment is on order under firm contracts, shall have a reactor as a source of heat, or whether it shall not. Consumers has until Saturday of this week (September 21) to secure a decision on the atomic-power negotiations, and to notify the manufacturers of the equipment as to the steam specifications.

These negotiations have been long and involved, it being approximately 2 years ago that Consumers' proposal was accepted by the Commission as a basis for negotiation. During that time we have made several appearances before the Joint Committee as you have studied the various aspects of atomic power. The various new sources in Nebraska have fully reported the progress (or lack of progress) of our negotiations throughout the entire period.

This project has had the support of the American Public Power Association through resolutions in 1955 and 1957. I would be glad to file copies if they would be of any benefit to the committee. It has had the support of the State, including the Governor, the Nebraska delegation in Congress, and responsible citizens throughout the State.

We trust that the objectives of this committee in speeding up the national development of atomic power will not be sacrificed by further delays resulting in abandonment of this project. It is clear that if the delay sought by these objectors occurs, Consumers' deadline with its manufacturers will have passed and the hopes for early completion of this reactor concept will be gone.

Representative HOLIFIELD. In reference to the latter part of your statement there, the committee has been informed that Senator Curtis and Senator Hruska and the Governor of Nebraska are very much in favor of the proposed arrangements and the congressional delegation also, and desire that the committee after appropriate review do waive the 45-day period.

Mr. SCHACHT. Thank you. The Governor has wired me as late as this morning further indicating that fact, if you do not have an expression from him. I understand now you do have it.

Representative HOLIFIELD. There is no ground for the fear of these cooperative purchasing groups having their power rates raised as a result of this venture?

Mr. SCHACHT. No, I cannot visualize that. We do not expect to sell this power to them or expect them to underwrite any part of this atomic-power venture. We have in the eastern two-thirds of the State, approximately 100,000 customers of our own.

Representative HOLIFIELD. It is your intention to integrate this power, at whatever cost it may be, into your complete system and to allocate its costs throughout the system rather than direct it to any one group.

Mr. SCHACHT. Well, Mr. Chairman, our contract negotiations with the Nebraska Public Power System are not yet complete, so the amount of power that we may be buying from them, in the years ahead, is not yet defined. It is our hope that we can tie this plant into the existing transmission grid in the State of Nebraska, so that it is utilized to the maximum extent.

We had not expected other public power districts to attempt to help underwrite any of our obligations under this contract.

Chairman DURHAM. What is your generating capacity at the present time?

Mr. SCHACHT. Our generating capacity at the present time in the eastern system is quite limited because we have been buying most of our power from the Nebraska Public Power System. We are proposing to build this plant ourselves, and it has been the subject of rather extended litigation in Nebraska, and the Supreme Court upheld Consumers' right to build the plant, and the need of a plant of this size in the spring of 1960, has been fully recognized. Up until the last 3 or 4 days I had never heard of any indication that someone felt it was not necessary in 1960.

Chairman DURHAM. Do you have to go through the courts to get permission to build this plant?

Mr. SCHACHT. No, sir, that has been all cleared. Several years ago that was done.

Representative HOLIFIELD. The fears of this group are unwarranted, then, that they are in danger of having rate raises as a result of this venture.

Mr. SCHACHT. I do not see why they have that fear at all. The question is the inclusion of an atomic reactor in this plant, which is really the only question before this committee. I do not think the committee has any problem as to whether Consumers should build a powerplant or not—that certainly is our problem.

Representative HOLIFIELD. But the group that has appeared indicated that the Federal Government has $145 million invested in enterprises in Nebraska. That is $100 million is invested in these consumer groups, these REA groups. As I understood the testimony, their fear was that a disproportionate amount of the cost of this venture, if the venture did prove to be a costly venture, on the part of the generating company, might be allocated to them rather than spread over the complete system. Of course, the committee would only be interested if it did jeopardize the Government's investment in these REA cooperatives.

Mr. SCHACHT. I cannot possibly see that. I can see no possible foundation for the fears that this atomic powerplant is going to do that.

Representative HOLIFIELD. Can you assure the committee that this power will be integrated and will be spread over the system, and not sold in a bloc to these groups of REA co-ops depending upon you to supply power? Can you give us that assurance?

Mr. SCHACHT. Well, Mr. Chairman, maybe I could explain it this way. We propose to use the power generated by this plant to serve Consumers 100,000 customers, or some part of them, and part of our load. We are not expecting to sell this power or asking the rural districts to buy part of this power at all.

Representative HOLIFIELD. Then there is no problem on their part of having their rates raised as a result of the generation of this power, if it happens to be more costly than conventional power.

Mr. SCHACHT. No; that is a problem which would fall only on Consumers' own customers, and those customers served by Consumers Public Power District.

Representative HOLIFIELD. You could not at this time serve these people; is that right?

Mr. SCHACHT. That is right, and we sell no power to these rural districts, nor do we buy power from them, except maybe a little backup some place, of a few dollars a month, but we do not sell them power, and we do not buy from them, nor do we contemplate any such arrangement.

Chairman DURHAM. Neither one of the groups; is that right? You don't sell to either one of the groups?

Mr. SCHACHT. We are buying power at present from the Loup and the Platte Districts, and we do not sell them any. We don't propose to, except possibly in some kind of an interchange arrangement, where there might be limited sales for a time, when one or the other has excess capacity. But we are not asking any of these groups to share any burdens that might develop in increased costs, because of this nuclear venture.

There were 1 or 2 questions you raised, Mr. Chairman, with respect to the contract or the negotiations which perhaps I might help clear up, if you would like.

Representative HOLIFIELD. We are glad to have your testimony.

Mr. SCHACHT. With regard to the matter of the patent rights, it is difficult to remember all of the conversations and discussions over a 2-year period on all of the phases of this contract. To the best of my recollection, and that of both Mr. Jones and Mr. Wilson, we had felt that Consumers was entitled to some rights in patents if they developed them in connection with their work in this atomic plant. We did not view it as anything of major consequence because as has been indicated, and I think we indicated to you this morning, most of those possibilities will develop out of the design and the construction of the atomic plant, which Consumers will not do.

Now, I think that if this question of the patent rights that we may retain is of any serious nature, I am sure that we are not adamant at all. Certainly we are entitled to a right to use any patents that we should develop but——

Representative HOLIFIELD. There is a long-standing principle that if the Government provides the money for a research and development program, that it retains the patent rights and makes them available not only to its Government facilities, but to other sections of the in-

dustry, because the money originally came from other segments of the industry in the form of taxes.

It is true that you are placing a $5 million contribution into this overall venture of some $51 million, and we assume that you are doing it for reasons which are based on good business principles. But we do not feel or at least the chairman does not feel that a $5 million contribution in a venture of this kind would justify a signing over the Government's patent rights in a $50 million venture to the Consumers of Nebraska. I don't think that you would contend that that would be equitable either; would you?

Mr. SCHACHT. I don't think that we have any hard and fast feelings. I think if we had a royalty free license to use what patents we might be able to develop, that would be satisfactory with us. It is not a major problem for us to the extent that it may be for the Government in establishing a principle of some kind.

Chairman DURHAM. How could you use them? You are not a manufacturer.

Mr. SCHACHT. I suppose the only way we could use them would be to turn around and sell them, and I am sure we have no intent of trying to get into that position, that we could go out and market some patents.

Representative HOLIFIELD. You know Congress is frequently charged with being give-away and some of us are sensitive when we see something along that line.

Mr. SCHACHT. We will be glad to adjust that clause.

With respect to the General Accounting Office approval, we realize that that is an open problem yet. We have been assured that they would give very early consideration and a prompt decision, and I am sure if their decision would be adverse, the Consumers would never consider signing the contract, and I don't know what AEC would do.

Representative HOLIFIELD. You speak of the date of the 21st as being a deadline and I was just wondering about that. If you do sign your contract as of the 21st for your specifications of your equipment, and an adverse decision comes through, you will be in an embarrassing position.

Mr. SCHACHT. There are two things that are possible, sir. One of them would be some type of a modification which would answer the problem that GAO has ruled against, or if it is not possible to go into this type of thing, then we would have to admit it and say that such a contract is not possible.

Representative HOLIFIELD. As a matter of completing the record, could you give us an estimate of what it would cost you to have a conventional steam-producing plant to complement this generating equipment which you are planning to install.

Mr. SCHACHT. You mean to replace it?

Representative HOLIFIELD. If you were going to build a conventional set of boilers, and burners, at this time, what would it cost you to build it and to bring your generating capacity to the full power?

Mr. SCHACHT. For this size plant it would be in the general neighborhood of $20 million.

Representative HOLIFIELD. So by increasing $5 million in this plant, you are to a certain extent obviating the necessity of investing $20 million in a steam-producing plant.

Mr. SCHACHT. Well, no, I misunderstood your question, because the $20 million is the complete plant, turbogenerator and all.

Representative HOLIFIELD. I wanted to differentiate between the steam producing and the turbine.

Mr. SCHACHT. The boiler itself would be approximately $5 million, and, in fact, that is how we arrived at the $5 million.

Now, we have done one thing in connection with this, that is not apparent from the contract. Because of the need of conventional power, and the fact that the reactor may have a couple of years of operation before it can be depended upon as a firm source of heat—we have ordered a conventional boiler, and propose to install it.

Representative HOLIFIELD. You are going ahead with a conventional boiler in any event?

Mr. SCHACHT. Yes.

Representative HOLIFIELD. And this is a supplemental.

Mr. SCHACHT. Yes, sir, that boiler was ordered back in May of this year. It is these specifications on it, for steam conditions, that we are confronted with.

Representative HOLIFIELD. Are there further questions?

Thank you very much.

Mr. Fields, will you and your group come back to the stand temporarily?

STATEMENTS OF GEN. K. E. FIELDS, GENERAL MANAGER; LOUIS H. RODDIS, JR., DEPUTY DIRECTOR, DIVISION OF REACTOR DEVELOPMENT; DELMAR M. MORRIS, ASSISTANT DIRECTOR FOR ADMINISTRATION, DIVISION OF REACTOR DEVELOPMENT; E. J. BLOCH, DIRECTOR, DIVISION OF PRODUCTION; DON S. BURROWS, CONTROLLER, DIVISION OF FINANCE; EDWARD DIAMOND, DEPUTY GENERAL COUNSEL; AND A. TAMMARO, ASSISTANT GENERAL MANAGER FOR RESEARCH AND INDUSTRIAL DEVELOPMENT—Resumed

Mr. FIELDS. Yes, sir.

Representative HOLIFIELD. The purpose of this part of the hearing is to obtain a status report on items in the authorization bill in which the committee is particularly interested. In this connection I would like to put into the record certain excerpts, a letter to Mr. Durham under date of August 29 from Mr. Fields.

A press release from the Atomic Energy Commission under date of August 30, inviting industry proposals for the design of gas-cooled power reactor.

An invitation for bids signed by Mr. W. Kenneth Davis, Director of the Division of Reactor Development, and two appendixes, A and B.

A letter from Senator Anderson to Chairman Carl T. Durham under date of September 2.

(The documents referred to follow:)

ATOMIC ENERGY COMMISSION,
August 29, 1957.

HON. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: The Commission is issuing a request for proposals from architect-engineers for the design of, and a report on, a 40,000 electric kilowatt natural uranium, graphite-moderated, gas-cooled, power reactor prototype as provided under project 58–e–14 of the recently enacted legislation authorizing appropriations for this Commission.

The contractor selected will recommend development work necessary for his design which can be carried out consistent with the desired schedules. Such work may be done by a nuclear engineering subcontractor or by other Commission contractors depending upon the circumstances. This procedure which is necessary to comply with the joint committee's directive does not foreclose the initiation of a more general development program or additional evaluation studies on gas-cooled power reactors at such time as the Commission deems appropriate.

Proposals are to be submitted not later than September 23, 1957, and award of a contract is expected shortly thereafter. The contract will require a report by March 1, 1958, which will serve as a basis for our report to your committee which is required not later than April 1, 1958.

A public release announcing our request for proposals will be issued tomorrow. A copy of the release is attached.

Sincerely yours,

K. E. FIELDS, *General Manager.*

ATOMIC ENERGY COMMISSION, WASHINGTON, D. C.

For immediate release
Friday, August 30, 1957

AEC INVITES INDUSTRY PROPOSALS TO DESIGN GAS-COOLED, NATURAL URANIUM-FUELED POWER REACTOR

The Atomic Energy Commission has invited United States architect-engineering firms experienced in reactor work to submit proposals for the engineering design of a natural uranium, gas-cooled, graphite-moderated nuclear electric powerplant of 40,000 electrical kilowatts capacity. September 23, 1957, has been set as the closing date for receiving proposals.

Development, design, and engineering work on this prototype plant has been authorized by the Congress. A report on the design, including cost estimates and schedule of construction, is to be submitted by the Commission to the Joint Committee on Atomic Energy of the Congress not later than April 1, 1958. Construction of the prototype powerplant has not been authorized by the Congress. No site for the plant has been selected.

Qualified firms interested in making such a proposal though not receiving a specific invitation to submit a proposal should address the Division of Reactor Development, United States Atomic Energy Commission, Washington 25, D. C.

ATOMIC ENERGY COMMISSION,
Washington, D. C.

GENTLEMEN: The Commission proposes to award a cost-plus-fixed-fee type contract for designing a natural uranium, graphite moderated, gas-cooled power reactor prototype. This project will comprise a nuclear reactor and powerplant including nuclear core, gas-cooling system, turbo-generating units, instrumentation, structures, utilities, and other appurtenances. Design must be completed as soon as practicable. To this end, preliminary design must be completed and the report thereon, required in appendix A, item IV attached, must be submitted by March 1, 1958.

It is anticipated that an architect-engineering firm will have prime responsibility for the work and that it will supplement its capabilities as necessary by association with a firm of proven ability in the design of reactors and other specialized nuclear components.

If you are interested in being considered for the engineering work on this project, you are invited to submit a proposal based on the requirements and data in appendixes A and B.

A contractor selection board will evaluate the replies received as a result of this inquiry. Selection will be based on an evaluation of proposals, supplemented to the extent considered necessary by the Commission by personal conference, in which all pertinent factors such as previous experience in similar work, availability of qualified personnel, and overall ability to perform and get underway with the job promptly upon award of contract will be taken into account.

Your reply should be addressed to Allan C. Johnson, Manager, Idaho Operations, United States Atomic Energy Commission, Post Office Box 1221, Idaho Falls, Idaho, and should be received not later than September 23, 1957.

Very truly yours,

W. Kenneth Davis,
Director, Division of Reactor Development.

Appendix A

ENGINEERING REQUIREMENTS

I. Develop design criteria and prepare an engineering design and cost estimate of a complete natural uranium, gas-cooled, graphite-moderated civilian power reactor and turbogenerator plant of 40,000 kilowatts (electrical) net. With the exception of fuel fabrication and processing facilities, all things necessary for the continued operation and maintenance of the plant shall be included in the design. Only minimum laboratory and administrative facilities shall be provided. Final site selection has not been made but the design and cost estimate will be predicated on a site at the National Reactor Testing Station, Arco, Idaho.

II. In establishing the design criteria the following shall be considered:

(*a*) A reactor optimized for the production of power from natural uranium is desired.

(*b*) The design shall be based on technology currently available to the United States AEC, with such development work as may be undertaken on a schedule consistent with initiation of a construction project in July 1958. Pertinent information on military, gas-cooled reactor projects will be made available.

(*c*) All United Kingdom information relating to Calder Hall to January 1, 1957, can be assumed to be available to all contractors.

III. Overall layout drawings on the entire system and its major components are required. Working drawings, details and specifications for construction, including a detailed estimate of the cost of construction based on the completed design, working drawings and specifications shall be provided. The requirements for the initial phase (title I) of the project are outlined below. Requirements and timing of the second phase will be developed in detail upon completion of title I.

IV. Preliminary design must be completed and the report thereon must be submitted by March 1, 1958. The report must include:

(*a*) Plans and outline specifications showing features and characteristics of the design proposed to meet the Commission's requirements. Detailed designs and specifications on unique components and systems shall be provided to the extent necessary to establish a realistic cost estimate for the entire system.

(*b*) Estimates of cost and time schedules for:

1. Completion of the design and working drawings. (Bearing in mind the need for expeditious completion.)

2. Construction. Separate cost and time schedules should be prepared for performance of construction by fixed-price and by cost-plus-fixed-fee contracts.

3. Developmental work.

(*c*) Operating cost estimate, including fuel element life estimates.

(*d*) Reactor hazards evaluation for the NRTS site, including possible containment requirements. Additional studies for other sites may be requested later.

(*e*) Outline procedures for startup, operation, and maintenance of plant including the basis for decision between shutdown fuel loading and fuel loading under power.

(*f*) Outline of fuel fabrication and processing requirements; and techniques available for accomplishment.

(*g*) The contractor's evaluation of the following:

1. Performance limits with the proposed design utilizing available technology and natural uranium.
2. The feasibility and effect on cost of future operation with slightly enriched loading.

APPENDIX B

EXPERIENCE RECORD AND BACKGROUND OF FIRM

I. For each type of design listed under 1 through 6 below, supply the following information:

(*a*) Location and name of project.
(*b*) Brief description of project.
(*c*) Client's name and address.
(*d*) Construction cost of the project related to your design.
(*e*) Total cost of your design work.
(*f*) Was design performed on a cost-plus-fixed-fee or firm-price basis?

1. The design of steam powerplants, both large and small, together with a brief description of the steam cycles employed.
2. Design of high-temperature and high-pressure gaseous systems with brief description of problems associated with thermal stresses, thermal shock, and welding of high alloy steels.
3. Design of chemical and industrial processes, including brief description of processes and methods of operation and control.
4. Design of ventilation and waste-disposal systems involving toxic materials, including brief description of toxic materials handled, problems of ventilation control and disposal of waste byproducts.
5. The development of new or unique equipment and processes such as original plant design evolved from laboratory and pilot-plant data.
6. Indicate specific examples where you have carried through the plant or process design, and also conducted preliminary operation and the preparation of operating procedures. Indicate in what manner you have performed these functions.

II. In connection with item I, indicate which, if any, of the above projects involve nuclear reactors and the extent to which your personnel participated in the nuclear design.

III. What part, if any, of of this proposed design work would you contemplate subcontracting to others? If the proposed subcontracting involves nuclear reactor design work, (*a*) list previous nuclear design work the subcontractor has performed; and (*b*) indicate the type of subcontract arrangements. Include statement on availability of subcontractor key personnel and staff similar to that required below.

IV. (*a*) Indicae where you would perform the design work. State the number of (1) engineers and (2) draftsmen you employ at that location on a full-time basis. How many of these would be available for assignment to this project on a full-time basis? State the extent to which staffing at this location can be supplemented from other locations of your firm. Indicate the total number of engineers and draftsmen employed by your company on a full-time basis if different from that above.

(*b*) Indicate average workload of firm, in terms of related construction costs, over the past 5 years. Indicate your current workload and percentage of completion.

V. (*a*) List names and brief experience record of key personnel available for assignment to this project. This shall include names of personnel to be assigned to head up the following functions:

1. Overall full-time project supervision (project manager).
2. Nuclear engineering.
3. Instrumentation engineering.
4. Structural engineering.
5. Electrical engineering.
6. Civil and sanitary engineering.
7. Mechanical engineering.
8. Field inspection of construction.

(*b*) Submit a proposed organizational chart showing the names and positions of company personnel, including those mentioned in (*a*) above, which you propose for assignment to this project from the project manager down through all key positions. This chart should be in sufficient detail to indicate chain of command and workflow for all major aspects of the work.

SEPTEMBER 2, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy.

DEAR MR. CHAIRMAN: This is with reference to the announcement on August 30 by the Atomic Energy Commission that it is soliciting bids from architect-engineering firms to submit proposals for the engineering design of a natural uranium, gas-cooled graphite-moderated nuclear electric powerplant.

As you know, this request for bids concerns a project which was recommended by the Joint Committee and authorized by the Congress as being necessary if the United States intends to maintain leadership in atomic technology. Also, as you know, despite the testimony of experts as to our present need for advancing natural uranium gas-cooled reactor technology, the AEC did not support such a project.

The AEC announcement is not clear that the contemplated design will be of an advanced type of reactor and not simply a copy of the existing Calder Hall reactor. The intended objective, of course, as shown by the committee's report is an improved and advanced concept of what the British to date have accomplished. The committee's report also makes clear that the prototype should be developed and designed in such a manner that enriched fuel elements can be tried out in the reactor.

In view of the importance of this project and the Commission's lack of support in this field of reactor development, I believe it is imperative that in accordance with its duties by law, the Joint Committee closely follow the administration of this project to insure compliance with legislative intent and full implementation of congressional authorization. I think it important that the Joint Committee be certain that it is kept fully and currently informed at all times relative to this project.

Sincerely yours,

CLINTON P. ANDERSON, *Vice Chairman.*

Representative HOLIFIELD. Now, Mr. Fields, we are going to try to expedite this, in view of the appointment which we know the chairman has.

Mr. FIELDS. Could I make just one remark about the discussions with respect to Consumers? That is, Mr. Leininger indicated there had been a wire sent to the Commission last week, and I have asked the representatives of the Commission who are here with me today, and we are not aware that we have received a wire, and I would appreciate receiving a copy from him, and I will check with him after the meeting. But we are not aware that we have received such a wire. It could be that it has been received. That is all I wanted the record to indicate.

Representative HOLIFIELD. There are a few questions I would like to go through as quickly as possible. That is on the gas-cooled reactor. Why was not the Joint Committee given a copy of the AEC prospectus which was sent out to industry?

Mr. FIELDS. I thought it was. Mr. Ramey asked me about it, and we forthwith gave him copies of it, and it was a complete oversight. It was intended to be a part of the letter, I believe. There was no intent not to forward this to you.

Mr. RODDIS. It was to be an enclosure to the letter.

Representative HOLIFIELD. The staff informs me that they did not receive it at the time that the letter went out, and they had to ask for it.

Mr. FIELDS. Well, the only thing I can think of, Mr. Chairman, is that, had we known that you wished it, it would have been there forthwith. It was as soon as Mr. Ramey asked me about it, and there are many proposals that we go out on, on any number of projects, where I am sure that we advise the committe, but we do not send them the proposals.

Representative HOLIFIELD. The committe is especially interested in this particular proposal, and the Chair does not need to announce it. The legislation of the last session of the Congress would indicate it. My next question is: Why was not the committee given copies of the North American reports on gas-cooled reactors while the proposal on gas-cooled reactors was being considered by the committee?

Mr. FIELDS. You have me at a loss, Mr. Chairman. I do not know the matter that you are referring to.

Representative HOLIFIELD. The committee was given large numbers of American Standards reports on gas-cooled reactors, but had to obtain the North American reports from the contractor.

Mr. RODDIS. Mr. Holifield, at least one copy, I believe, was sent up under a date which I will have to verify. I gave Mr. Ramey two more copies this morning, when I found out that he wanted more. But there was certainly no intention to withhold copies from the Joint Committee.

Representative HOLIFIELD. This report was available during the time that legislation was under discussion. We did not have access to it, however, until the last days of Congress.

Mr. RODDIS. I will have to verify the dates on the letters, but it was my understanding that a copy was sent up here early.

Mr. RAMEY. The report was made available only by the contractor and after a request by the committee staff. It was never sent up by the Commission.

(With regard to this point, the AEC subsequently informed the Joint Committee, as follows:)

Concerning AEC submission to the Joint Committee of copies of the North American report evaluating the Calder Hall project, a check of our files indicates that no copies of this report were sent to the Joint Committee prior to September 17, when they were furnished to Mr. Ramey. (See also Appendix III, p. 65.)

Representative HOLIFIELD. The committee does feel that the Commission should have presented that report, and at the time when the matter was of serious consideration both from the standpoint of the committee hearings and from the standpoint of legislative action on the floor. It was available, and we feel that the Commission did not fulfill its obligation to the committee of keeping the committee fully informed.

Mr. FIELDS. I am sure, Mr. Chairman, I will have to disagree with you on that point, insofar as any intent on our part was concerned. As far as I know, we did not realize that this would be a part of the considerations. The questions of proposals and reviews of the gas-cooled reactor project—we had commented to the committee on our views on this at times by letter. I don't recall where the Commission as such—we did testify with respect to our views on that, sir.

Representative HOLIFIELD. The economics of the report would have been valuable to the committee.

Mr. FIELDS. I am sure we regret it did not get to the committee. I just do not know, and I will have to review the circumstances of it.

Representative HOLIFIELD. Have you, General Fields, or Mr. Tammaro, read the committee report with respect to utilizing Westinghouse and Admiral Rickover, page 26:

The committee is of the opinion that the smallest practical prototype of a natural uranium, gas-cooled reactor should be designed and constructed as soon as practicable. It is believed that the reactor developed will represent an advance on the Calder Hall technology. It is understood that the gas-cooled, prototype reactor contemplated in the bill can be so designed as to operate on natural uranium fuel initially, but later can test out the feasibility of slightly enriched fuel elements.

In view of the availability of the AEC installation at Bettis and Idaho, including able designers and engineers of the Bettis group, and the willingness of Admiral Rickover to undertake direction of the gas-cooled-reactor project, it would appear essential that this project be assigned to the Naval Reactors Branch under Admiral Rickover.

In the committee's view, the design and construction of a gas-cooled prototype under Government contract as outlined above would have the following advantages—

And they are listed, and they will be included in the record at this point—

(1) It would enable this country to obtain gas-cooled technology and knowhow rapidly by utilizing the well-rounded Westinghouse Bettis group and facilities under Admiral Rickover's direction.

(2) Although the best way to get atomic technology is through actual experience, the cooperative arrangements between the British and the AEC Naval Reactors Branch on naval reactor work, and United States rights to Calder Hall technology under a direct-contract operation would assure that all appropriate technical information is brought to bear in developing an advanced gas-cooled reactor prototype.

(3) Since the moderator would not be heavy water, the reactor and its development would differ considerably from the gas-cooled, heavy-water reactor sponsored by the the Florida power group and Dr. Zinn. The size of the 2 reactors also differs markedly, 40,000 to 140,000 kilowatts. However, information and data developed on common problems in the gas-cooled field would be readily available to Dr. Zinn and his associates.

I am sure you are aware of the committee's feelings on that point.

Mr. FIELDS. Yes, I am.

Representative HOLIFIELD. Has Westinghouse been contacted in regard to making a study on this?

Mr. FIELDS. They have been given a copy of the proposal, as have a number of other firms, and we understand that they—and this is informally—are considering arrangements with several different architect-engineers actually with respect to this.

Representative HOLIFIELD. You have had a number of contacts?

Mr. FIELDS. This is all informal, and the date for receipt of proposals I believe is the 23d, next Monday; yes, sir.

Representative HOLIFIELD. You have had proposals in from the Bettis group as well as others?

Mr. FIELDS. We have had discussions and we understand informally what they are considering, and their proposals are not in from any source that I am aware of at this point. There is considerable interest in this, I might say.

Mr. RAMEY. Would this be the Bettis group? Westinghouse has two organizations. They have a private commercial outfit, and then they have the Bettis government-financed group. Is it understood that the Bettis group is submitting a proposal?

Mr. FIELDS. I am not aware that the Bettis group is submitting a proposal.

Mr. RAMEY. Would they be permitted under your announcement?

Mr. FIELDS. Our proposal has gone out to architect-engineering firms, and indications are that we would expect that they would associate themselves with groups who had the capability to perform the necessary nuclear studies and analysis here to come up with this particular report. It is not proposed that if there is a large-scale development to be undertaken here it could be undertaken in conjunction with this $3 million authorization project. We have not foreclosed what might be done on a full long-term development project with respect to gas-cooled reactors. We are attempting to outline the engineering aspects, cost schedules, and what would be involved so that we could move quickly into construction, and also to outline a development that would be necessary in conjunction with such a project, and to have it in hand so that it can be submitted to Congress as required by law on the 1st of April. That is the reason for moving thus rapidly in this regard.

Representative HOLIFIELD. The committee, of course, appreciates the fact that the Commission has moved into this and is taking action on it.

Mr. FIELDS. The Bettis field group is not an architect-engineering firm. They are a development firm and they do not even do the architect-engineering for the PWR. They have done the development work. So this is the problem that was posed to us. We have considered all aspects of this, and I want to assure you as far as I know, Mr. Chairman, we are moving as rapidly as we can on this, and with a real effort to do this in a manner which will present to the Congress all of the things that are necessary for there to be a decision made next spring on whether or not this should be constructed full scale.

Representative HOLIFIELD. Is it your concept that the report will cover an advance on the Calder Hall concept, or does the language of your proposal preclude an advance on the so-called Calder Hall concept and confine it to technology which is now available to the AEC? Either in your own files or from your agreement with Great Britain.

Mr. FIELDS. It is limited to basing it on present technology available, with such development and improvement as could be accomplished consistent with a time scale of starting construction on the 1st of July of 1958, which is a requirement of the authorization. That is, as we understand it.

Representative HOLIFIELD. I would like to clarify that. I was somewhat surprised when I read it and I appreciate the speed with which you are moving, and in view of the fact it was realized that there was a difference of opinion on going into this project. But where do you get the July 1 date to initiate construction?

Mr. FIELDS. I thought that was in the report.

Representative HOLIFIELD. I am sure you will not find it in the legislation. It seems to me that rather than being of value to the project, this might impose such a rigid requirement that it would preclude the study almost to a failure to begin with.

If you insist because the study was to be submitted on April 1 that construction should start on July 1, I have not had a chance to talk with any of the manufacturers, but I am wondering if in that particular requirement you are not processing in such a way that you would eliminate some interest in the study.

Mr. RODDIS. I think that remains to be seen, but from the indications we have at the moment that won't be true. Now, start of construction on July 1 does not mean that you start building huge structures at that time, but you do start entering into contracts for the construction by that time. That would be the way we anticipate it. The project would be initiated.

Representative HOLIFIELD. This was so much faster than anything that has occurred under any of your proposals that I become just a little bit surprised. After using 27 months to negotiate with Consumers, I am rather bewildered by this sudden show of speed on the part of the Commission. I don't want to put you in the position of complaining because you do hurry and complaining because you don't, but I think that there is something there. I would like to read the language of the act here. It says:

the Commission shall proceed with sufficient design work together with the appropriate engineering work necessary for the Commission to begin construction as soon as practicable after the authorization by the Congress, of a large-scale natural uranium power reactor or prototype.

Mr. FIELDS. I am sure, if we had interpreted that to be July 1, 1959, we might be hearing in another vein with respect to this.

Mr. RAMEY. Is it your determination that it is practicable to initiate a construction project on July 1, 1958, after the submission of this report on April 1? That language would require the Commission to make this judgment as to practicality, and it seems that there could be some judgment or some determination that that is a little hasty. You could make a determination for September which might give a little more time to get a design underway on a more advanced type of reactor. You could also have made a determination that the Congress would not authorize it before July 1. This year Congress did not authorize these projects until August.

Mr. FIELDS. Well, the difficulty may be in our understanding each other here. That is the description of what an advanced type is. When you take other factors in the legislative history, then I think that you must have a clearer definition of what an advanced type is, and if advanced type is an enriched type reactor of a different sort entirely, rather than just this type of an arrangement, then I would not read that the legislative history says we have the latitude to do this. But certainly we have, we believe, the belief that it is practical to build one, if it is desired to, or if the feasibility shows it is attractive to do so, and then this is within the region of practicality of when you could begin construction. That is, to begin a construction project; involved with that will be some development work that will be necessary further to do.

It might have improvements, I would hope, over the Calder Hall type of reactor itself, and it would not be a long 4- or 5-year development project, and we have not thought of it in those terms, before you build one of these, so that you get the most advanced type reactor, say, 4 years from now, but you start construction. But it would be certainly an improvement over the Calder Hall reactors that are now in operation.

Mr. RAMEY. Or the CEA reactor, the British-type reactor being built for commercial purposes. As I understand it, the present Calder Hall is a dual-purpose one.

Mr. RODDIS. This depends upon what the definition of natural uranium graphite moderated reactor is. If it is only a natural uranium machine operated to low burnups, I don't think that there is any question that one could be built. There is a question as to whether it is an economic machine in that sense. This is Calder Hall. This CEA unit which implies a high burnup fuel element involves a certain amount of development, a substantial amount of development, we believe.

I rather doubt that development could all be completed before you started construction. But we have started construction of other reactors before we had all of the development problems solved.

Mr. RAMEY. Shouldn't it be made clear in your prospectus that you would at least like to have it as far developed as the CEA type.

For example, your North American report, in certain cost estimates assumed that you could reach the higher temperature fuel elements of the CEA type, as I understand it. Should not your prospectus make that clear to these people, so that when you come in with this sort of thing you will be doing that?

A very short time schedule, or a limited amount of technology, would require you just do it as a carbon copy.

Mr. RODDIS. That in part depends upon your definition of a natural uranium graphite moderated reactor which is what the authorization states. We have asked, if you will note the last page of appendix 1, of the proposal or the invitation, for two items. Item (g) we ask for the contractors' evaluation of the following:

(1) Performance limits with the proposed design, utilizing available technology and natural uranium; and (2) the feasibility and effect on cost of future operations with slightly enriched loading.

Now, to my mind, a slightly enriched loading may be achieved either through uniform slight enrichmnt of through the use of natural uranium and what are called special ore seeds. Certainly the average load of the machine is in that case a slightly enriched one, and that has been our interpretation.

I do not know whether the CEA reactors are going to operate with slightly enriched uranium or with natural uranium.

Representative HOLIFIELD. I only regret that we can't go into this matter fully, because we are going to have to adjourn because of other commitments. We have run over at the present time.

Before we adjourn I want to make this statement: The committee does not desire hasty action or the imposition of impracticable and impossible requirements on the study of this matter, nor the initiation of the project under such rigorous terms that the Commission can come up and say: "Well, we have not found it practicable, and we rule against it because of the time limitation involved."

There is no July 1 initiation of construction in the act, and this is a date of your own conception. The date for the presenting of a study is April 1, in the act, and the words "as soon as practicable after authorization by the Congress," certainly give you more latitude than July 1. Personally, I think that the imposition of this type of a rigorous demand that might contribute to a lack of interest on the part of some people if they knew that they had to initiate construction within 90 days after they submit it to you, and before you had a chance to properly evaluate it or the Congress itself even had a chance to

evaluate it and act upon it from the standpoint of authorizing the money to do it.

So the committee is going to watch this very closely, and we expect the Commission to act in good faith and to follow the legislative history which has been written on the subject. We do not expect a duplicate of the obsolete Calder Hall reactors. We believe that there can be an advanced concept, and an improvement over the Calder Hall, and personally I do not support any appropriation which would be to build a duplicate of the Calder Hall reactor, I consider it is obsolete, and I consider that the new natural uranium gas cooled reactor in Britain are a great deal more advanced than the Calder Hall design, and I think it is therefore up to American scientists and up to the Commission to look at this thing in that light, rather than the light of doing something which the committee did not ask to be done.

The committee specifically said it is "believed that the reactor developed should represent an advance on the Calder Hall technology, with, for example, higher temperature fuel elements."

You are aware of the development of certain materials which does allow higher temperature elements, and more evidence, and which is being used in the new reactors in Britain.

You are also aware, no doubt, of a different type of enrichment rather than the U–235 enrichment which is being experimented with.

My next question was going to be on your plutonium recycle. Are you proceeding along the line of getting some real thinking done on that, and planning done on that line?

Mr. Roddis. Mr. Holifield, in addition to this specific invitation, we are doing four other things. In the gas-cooled machine, we are doing other things than just this thing. We have asked Dr. Zinn's group to conduct an evaluation, and our Oak Ridge Laboratory to do it in addition to the Atomic International and American Radiator or American Sanitary.

Dr. Zinn is in England this week with Mr. Davis, looking at this very closely, and then they are going to France, because the French have some different approaches to this problem.

On the plutonium recycle reactor project, as you know, work has been under way at Hanford for approximately a year and a half on this. Preliminary design has in fact been nearly completed on the plutonium recycling reactor itself. Meanwhile, the development program on the making of plutonium fuel elements, which is after all the whole purpose of the plutonium recycling reactor, is to test such elements, has been progressing at Hanford, at Los Alamos, and at the Argonne National Laboratory. We are, of course, at each of these sites posed some difficult problems on facilities, because to work with plutonium requires a certain amount of, or rather a large amount of special facilities.

The first of these facilities, especially devoted to the reactor program, is being equipped at Argonne now. That is the building and ventilation is finished, and the equipment is being placed in it. In last year's authorization bill was contained the fuel technology center there, and the addition to the Hanford fuel technology center. So that we are doing what we can in existing facilities and we are trying to build facilities which can be committed specifically to the reactor program because at the present time we are always involved in inter-

ference with weapons work where we just received a big setback last week in one area.

The reactor itself, the people from Hanford are in fact in here today, and we expect in that case to do the architect engineering work on it at Hanford, with GE. You see both GE and Du Pont are the two installations that have always done their own architect engineering work, and we expect to complete design of that shortly, and we expect to actually start construction probably some time in the winter. That is the actual digging of a hole. That reactor is going to be a heavy water tube type reactor, vertical geometry, if you are interested we have a considerable amount of design detail on it available.

Representative HOLIFIELD. That is encouraging.

Mr. RODDIS. I hope I have made clear that the plutonium recycling program is not only the plutonium recycle reactor, because the making and testing of fuel elements to go into that is what is important, and on that we have had to create these other facilities, and the whole program is moving as well as could be expected.

Representative HOLIFIELD. That is encouraging.

We are going to have to call this meeting to a close at this time. We will look forward to having a review of this in more detail in January when we come back.

Mr. FIELDS. Could I have the record show that with respect to the special-purpose reactor for production of plutonium, we advised Mr. Durham as to what we were doing, and we have had representatives of General Electric and of Du Pont in yesterday and today with respect to preliminary studies as to the actual construction of such a reactor and the design work for it in accordance with the $3 million authorization in the bill.

(The communication referred to follows:)

ATOMIC ENERGY COMMISSION,
September 4, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: Public Law 85–162, 85th Congress, includes authorization for the expenditure of $3 million for development, design, and engineering on a production reactor for special nuclear materials (project 58–b–8).

Within the next few weeks, we plan to discuss with personnel of the Hanford and Savannah River offices and of the General Electric and du Pont Cos., their proposed plans to undertake work on reactor types they believe feasible of providing increased productive capacity in accordance with this authorization. Upon completion of these preliminary discussions, we plan to initiate development and design work on a specific reactor type or types so as to permit submission of a report to the Joint Committee on Atomic Energy by April 1, 1958.

Sincerely yours,

R. W. COOK, *Acting General Manager.*

Representative HOLIFIELD. You are excused, and thank you very much.

I want to ask the American Machine & Foundry man, Mr. Snapp, who on my instructions, the staff contacted and requested to return to this meeting, in view of this other appointment, will you file a statement with the committee within the next 2 or 3 days, in regard

to the reasons for the changing of your position on the Elk River reactor?

Mr. SNAPP. We will be glad to do that, Mr. Chairman.

(The statement referred to will be found on p. 14.)

Representative HOLIFIELD. Do you have a prepared statement?

Mr. SNAPP. No; we do not.

Representative HOLIFIELD. Very well. We will adjourn now.

(Thereupon at 4:15 p. m., the hearing was concluded.)

APPENDIXES

APPENDIX 1

Resolution

Whereas section 111b of Public Law 162, 85th Congress, provides that before the Commission enters into any arrangement the basis of which has not been previously submitted to the Joint Committee on Atomic Energy and which involves appropriations authorized by subsection a of section 111, the basis for the arrangement which the Commission proposes to execute shall be submitted to the Joint Committee, and a period of 45 days shall elapse while Congress is in session: *Provided, however*, that the Joint Committee, after having received the basis for a proposed arrangement may by resolution in writing waive the conditions of or all or any portion of such 45-day period, and

Whereas the Commission by letter dated September 13, 1957, submitted to the Joint Committee the bases of proposed arrangements with the Consumers Public Power District of Nebraska, and with the Northern States Power Co., of Minneapolis, Minn.; and

Whereas the Commission requested waiver of the 45-day period by the Joint Committee as to these two proposals; and

Whereas the Subcommittee on Legislation of the Joint Committee considered the Commission request at a public hearing on September 17, 1957, and

Whereas the members of the Joint Committee have been polled as to the request of the Commission: Now, therefore, be it

Resolved, That, pursuant to section 111b of Public Law 162, 85th Congress, the Joint Committee hereby waives requirements of the 45-day period while Congress is in session as to the proposals of Consumers Public Power District of Nebraska and the Northern States Power Co., of Minneapolis, Minn., as requested by the Commission letter dated September 13, 1957, a copy of which (with enclosures) is attached to this resolution.

Dated this 19th day of September, 1957.

(The letter and enclosures referred to will be found on p. 3.)

APPENDIX 2

Atomic Energy Commission,
Washington, D. C., September 20, 1957.

Hon. Carl T. Durham,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

Dear Mr. Durham: In Mr. Vance's letter of September 13, 1957, to you transmitting the bases for proposed cooperative arrangements with the Consumers Public Power District and Northern States Power Co., we stated that we were submitting to the Comproller General a question in connection with each proposed contract as to our authority to enter into certain commitments for the operating period.

We have been advised by the Comptroller General that "we believe that the Commission is authorized to enter into contractual arrangements of this type with Consumers, and we will not be required to object thereto." A copy of that letter is attached for your information.

The obligations which the Commission proposed to undertake for the operating period included payments for excess fuel costs and for certain maintenance and related expenses totaling an estimated $8 million. While the Comptroller General's letter specifically refers only to the fuel cycle costs, it also refers to

the total figure of $8 million and we have been assured by the General Counsel of the General Accounting Office that the principles stated in the letter are intended to be applicable to maintenance and related costs as well.

Sincerely yours,

K. C. FIELDS, *General Manager.*

COMPTROLLER GENERAL OF THE UNITED STATES,
Washington, September 19, 1957.

Hon. LEWIS L. STRAUSS,
Chairman, Atomic Energy Commission.

DEAR MR. STRAUSS: Reference is made to letter from the Deputy General Manager dated September 12, 1957, requesting decision whether we would object to certain provisions of a proposed contract between the Commission and Consumers Public Power District of Nebraska. The proposed contract is the third under the first round of the Commission's power demonstration reactor program, and provides, generally, for the construction and operation of a sodium-graphite nuclear reactor to produce electricity. Both the Commission and Consumers will participate in the cost of necessary research and construction, and Consumers will furnish the Commission with all pertinent information developed prior to and during a 5-year operating period.

The particular contract provisions which have raised the question now presented to us call for the Commission to reimburse Consumers for certain fuel cycle costs incurred during the 5-year period beginning with the commencement of actual plant operation. Essentially, the arrangement proposed is that Consumers will bear such costs up to the cost of conventional fossil fuels and the Commission will bear any excess. The doubt which exists as to the propriety of making such contractual commitments arises from the general rule stated in decision B-130815, dated September 3, 1957, to the effect that funds appropriated to the Commission for the needs of a particular fiscal year could not be obligated for the needs of future fiscal years. In our opinion, the legislative history of Public Law 85-162, approved August 21, 1957, which authorized appropriations for the Commission for its power demonstration reactor program for the fiscal year 1958, and the action of the Congress in appropriating funds for the Commission in accordance with that authorization act, clearly show congressional approval of the proposed contractual arrangements.

As reported out by the Joint Committee on Atomic Energy, the authorization act would have required the Commission to make somewhat different contractual arrangements with Consumers and with the sponsors of projects under the second round of the power demonstration reactor program. After considerable discussion on the floor of Congress, the authorization act was changed to permit the Consumers project to be carried out as previously contemplated. The Joint Committee and the Congress were fully apprised of the fact that the contemplated arrangements with Consumers included provision for the Commission to bear a part of the fuel cycle costs during a 5-year operating period. See, for example, pages 13972-13973, 14486, and 14487, Congressional Record, August 20, 1957. The amount included in the authorization act included $8 million specifically justified to the Joint Committee as fuel cycle costs under the Consumers project.

In view of the legislative history, we believe that the Commission is authorized to enter into contractual arrangements of this type with Consumers, and we will not be required to object thereto. In view of the need for expeditious decision on the matter, no other aspects of the proposed contract have been considered.

Sincerely yours,

JOSEPH CAMPBELL,
Comptroller General of the United States.

APPENDIX 3

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington D. C., November 21, 1957.

Hon. CARL T. DURHAM,
Chairman, Joint Committee on Atomic Energy,
Congress of the United States.

DEAR MR. DURHAM: You will recall that during the September 17, 1957, hearings before your committee a question was raised regarding the circumstances under which the North American Aviation, Inc., report on the Calder Hall type nuclear powerplant was submitted to the JCAE. I have asked the Division

of Reactor Development to look into this matter and they have provided me with the following information.

This report is actually contained in two parts. The first was sent to us on January 25, 1957; the second was dated June 28, 1957. Thus, the complete report giving a comprehensive evaluation of this type of reactor was first available to us early in July.

Despite a delay in forwarding the reports it was certainly not our intention to keep these reports from the JCAE. Our letter of May 16, 1957, reporting on the status of the United Kingdom nuclear power program referred to the conclusions reached in the January report. In early August, Mr. Hollister of the JCAE staff called the Division of Reactor Development regarding the availability of these reports. He was advised that due to the shortage of copies of the reports we could not supply him with copies at that particular time. He was, however, invited to use the copies of the report on file in the Division of Reactor Development. Subsequently, when the local NAA representative furnished copies of the reports to the JCAE it was done with our approval.

We are, of course, very aware of our responsibility for keeping the JCAE informed of all aspects of our program. We shall make every effort in the future to provide the JCAE with copies of reports of this type as soon as possible after they are received.

Sincerely yours,

R. W. Cook, *General Manager.*

(Editorial Note.—Compare with AEC statement on June 26, 1957, during authorization hearings at page 563. Hearings before the Subcommittee on Legislation of the Joint Committe on Atomic Energy, Congress of the United States, 85th Congress, 1st session, on Authorizing Legislation for AEC's Fiscal Year 1958 Construction Budget.)

WEST BERLIN REACTOR

MARCH 6, 1957

CONGRESS OF THE UNITED STATES,
SUBCOMMITTEE ON AGREEMENTS FOR COOPERATION,
JOINT COMMITTEE ON ATOMIC ENERGY,
Washington, D. C.

The Subcommittee on Agreements for Cooperation met, pursuant to call, at 10 a. m., in the committee room, the Capitol, Hon. John O. Pastore (chairman of the subcommittee) presiding.

Present were: Representative Carl T. Durham (chairman of the full committee), John J. Dempsey, Sterling Cole, James E. Van Zandt, and James T. Patterson; Senators John O. Pastore (presiding), Bourke B. Hickenlooper, and John W. Bricker.

Staff members present: James T. Ramey, executive director; Messrs. George Norris, Jr.; George E. Brown, Jr.; Wade Dickenson, and Hal Hollister.

Representatives of the Atomic Energy Commission: Hon. Thomas E. Murray, Commissioner; R. W. Cook, Deputy General Manager; Allen J. Vander Weyden, Deputy Director, International Affairs; L. H. Roddis, Deputy Director, Division of Reactor Development; N. F. Sievering, Division of Reactor Development; Paul Foster, Assistant General Manager for International Activities; John A. Hall, Director, Division of International Affairs; A. A. Wells, Office of the General Counsel; and Bryan LaPlante, special assistant to the General Manager.

Representatives of the Department of State: Gerard Smith, special assistant to the Secretary of State for Atomic Energy; Raymond E. Lisle, Deputy Director of the German Office; William K. Miller, economic officer for the German Office; Richard Kearney, legal adviser for German affairs; J. Robert Schaetzel and Robert M. Winfree, Office of Mr. Smith; and Stanley Cleveland, European Regional Affairs Office.

Senator PASTORE. Gentlemen, if we are ready, we ought to get started.

This is a meeting of the Subcommittee on Agreements for Cooperation. It is to discuss the legislation needed in order to permit a research reactor of the swimming-pool type to be built in West Berlin. I understand that the State Department and the Atomic Energy Commission are both represented here and that they have statements. I think we ought to begin with the Atomic Energy Commission if that is satisfactory.

STATEMENTS OF THOMAS E. MURRAY, COMMISSIONER; R. W. COOK, DEPUTY GENERAL MANAGER; ALLEN J. VANDER WEYDEN, DEPUTY DIRECTOR, INTERNATIONAL AFFAIRS; L. H. RODDIS, DEPUTY DIRECTOR, DIVISION OF REACTOR DEVELOPMENT; N. F. SIEVERING, DIVISION OF REACTOR DEVELOPMENT; PAUL FOSTER, ASSISTANT GENERAL MANAGER FOR INTERNATIONAL ACTIVITIES; JOHN A. HALL, DIRECTOR, DIVISION OF INTERNATIONAL AFFAIRS; A. A. WELLS, OFFICE OF THE GENERAL COUNSEL; AND BRYAN LaPLANTE, SPECIAL ASSISTANT TO THE GENERAL MANAGER, ALL OF THE ATOMIC ENERGY COMMISSION

Mr. Hall. If that is agreeable to Mr. Lisle.

Mr. Lisle. Surely.

Representative Cole. Mr. Chairman, may I state for the record, in case anybody may wonder why this bill carries my name rather than that of some other member of the committee or the chairman, that a week or so ago the chairman, Mr. Durham, inquired if I would care to introduce the bill. I said that I was ready to cooperate in any way possible and he suggested that I introduce it. That is the reason it has my name.

Mr. Hall. Mr. Chairman, may I proceed?

Senator Pastore. All right.

Mr. Hall. In the furtherance of an important foreign policy objective the Department of State has for the past few months been consulting with AEC in order to work out an arrangement under which the United States could cooperate with West Berlin in the peaceful uses of atomic energy. In particular, the Department has advised the Commission that the authorities in West Berlin are enthusiastic about obtaining a research reactor at the earliest practical moment and that West Berlin is prepared to provide all funds necessary to its construction and operation.

In the initial discussions concerning the development of a possible arrangement for the construction of a research reactor in West Berlin, consideration was given to a swimming-pool reactor. Subsequently, however, the West Berlin authorities decided to purchase and have constructed a 50-kilowatt water boiler research reactor to be located in the American sector of Berlin in an isolated forest area about 15 miles from the center of the city, and have undertaken negotiations with North American Aviation Corp. for this purpose.

The Department of State has advised that a 2,500-kilowatt swimming-pool reactor purchased from the Soviet Union is now under construction in Dresden in East Germany and that a research center will be established there. Further, we are informed that the presence of a United States reactor in West Berlin would go far in counteracting any phychological advantage that might accrue to international communism as a result of this project.

The Commission has explored the possibility of cooperating with West Berlin under the present Atomic Energy Act so as to permit the export of the desired reactor and its fuel to Berlin. Inasmuch as West Berlin does not constitute a nation capable of making an agreement for cooperation in accordance with the Atomic Energy Act of 1954, the Commission believes that the legal basis for the export of a reactor

from the United States or the distribution of special nuclear materials to Berlin is unclear. The benefits of the existing Agreement for Cooperation with the Federal Republic of Germany are not available to West Berlin, since West Berlin is not under the jurisdiction of the Federal Republic. Accordingly, in the judgment of the Commission, an amendment to the Atomic Energy Act is needed to permit the United States to cooperate with West Berlin in a manner similar to the cooperation which is permitted with nations.

The proposed amendment would authorize cooperation with West Berlin by permitting the distribution to West Berlin of source, special nuclear, and byproduct material, permit the export of reactors to West Berlin, and authorize the conduct in West Berlin of activities covered by section 57a (3) of the act. Restricted data would not be authorized for transmission under this amendment.

An agreement for cooperation pursuant to the proposed amendment would be entered into by the Federal Republic of Germany on behalf of West Berlin inasmuch as under existing arrangements the Federal Republic carries on foreign relations in behalf of West Berlin. However, the terms of such an agreement would require West Berlin to make the guaranties specified in section 123 of the act with the approval of the Allied commandants.

Senator PASTORE. Congressman Cole.

Representative COLE. I notice, Mr. Hall, that your statement has identified the locality as West Berlin and the bill refers to it as Berlin. Is there any reason why the law should not identify it as West Berlin rather than Berlin?

Mr. HALL. I prefer that my State Department colleague here answer that.

Representative COLE. Let's have the other statement and then we can ask our questions.

Senator PASTORE. All right, then, would you identify yourself for the record?

STATEMENTS OF GERARD SMITH, SPECIAL ASSISTANT TO THE SECRETARY OF STATE FOR ATOMIC ENERGY; RAYMOND E. LISLE, DEPUTY DIRECTOR OF THE GERMAN OFFICE; WILLIAM K. MILLER, ECONOMIC OFFICER FOR THE GERMAN OFFICE; RICHARD KEARNEY, LEGAL ADVISOR FOR GERMAN AFFAIRS; J. ROBERT SCHAETZEL AND ROBERT M. WINFREE, OFFICE OF MR. SMITH; AND STANLEY CLEVELAND, EUROPEAN REGIONAL AFFAIRS OFFICE, DEPARTMENT OF STATE

Mr. LISLE. My name is Raymond Lisle, Deputy Director, Office of German Affairs, Department of State.

As the committe is doubtless aware, the United States has unusual legal and political interests and responsibilities in Berlin. The United States is an occupying power in Berlin. It has on numerous occasions reaffirmed its intention to maintain the security and welfare of the city. Although we discontinued economic assistance to the Federal Republic of Germany some time ago, in line with our special status and our responsibilities in Berlin we have continued to extend economic assistance there.

Senator PASTORE. Before you go further, how do you distribute aid there? To what Government or to what agency? How does that operate?

Mr. LISLE. It is distributed to the government of Berlin—the executive agency which is known as the Senat.

Senator PASTORE. All right.

Mr. LISLE. The unique situation of Berlin has brought us not only responsibilities but opportunities of the greatest political importance. It is an enclave—an island entirely surrounded by the Soviet Zone of occupation, but is free from Soviet control. Its life and achievements are far more accessible to the people of Soviet-occupied Germany than those of any other part of the free world. As a result they have come to be a significant illustration of the moral and material advantages of the free world and a constant and effective challenge to the efforts of the Communist authorities to develop acceptance of their control. We make a great deal, I must say, of the show window concept of Berlin and the extent to which it provides us with an opportunity to demonstrate the achievements of the western free world to the people of the Soviet Zone.

As the Atomic Energy Commission has informed the committee, the western sectors of Berlin are not under the jurisdiction of the Federal Republic of Germany, and the benefits of the agreement for cooperation with the Federal Republic are not available to Berlin.

It might be useful to explain briefly the status of the western sectors of Berlin and the situation with respect to atomic energy matters.

Berlin continues to be under military occupation. The United States, British, and French commandants retain supreme authority in the western sectors and, acting jointly, constitute the ruling body in those sectors. The United States commandant exercises this authority in the United States sector. The Soviet Union has no voice in the government of the western sectors.

The commandants have delegated a substantial degree of their authority to the Berlin Senat, which is the governing body in the Berlin city government. At the present time, it has not given the Senat any authority with respect to the control of atomic energy activities. These controls are exercized by the commandants under an occupation law. It is contemplated, however, that the commandants will delegate a substantial degree of authority in this field to the Berlin Senat as soon as the Senat has formulated a suitable atomic energy control law. The commandants, however, will continue to have a power to intervene should security require them to do so.

There is great interest in nuclear research on the part of the scientific community in Berlin, as well as in the Berlin city government and among responsible industrialists. The two universities in West Berlin, the Free University and the Technical University, are jointly forming an Institute for Atomic Research which will bring together the research and training facilities of the two universities in this field and operate the reactor when it is obtained.

Ambassador Conant, who has a very considerable knowledge of atomic energy matters, is convinced that Berlin can make very effective use of a research reactor. Dr. Conant has told us—and this is a quotation from a letter from him that—

> the scientists associated with the two Berlin universities have not only the interest but the technical capability to make very good use of a reactor.

I may say that Ambassador Conant with his background has taken a very special interest in this project and considers it highly desirable.

In view of the enthusiasm with which the Berliners (and the German Federal Government) are pushing the concept of a research reactor in Berlin and the recognized technical capabilities of the Berlin institutions for using it, we believe it will be politically and psychologically unfortunate if it should not be possible for the United States to cooperate. Further, the erection of a research reactor in Berlin with United States cooperation would provide a highly desirable confirmation of continuing interest and confidence of the United States in Berlin and in its support. It would do much to offset the psychological advantage the Communists are hoping to derive from the reactors they are planning in the Soviet Zone of Germany.

Finally, a few words about the manner in which we are proposing to cooperate; that is, the extension to Berlin of the agreement for cooperation with the German Federal Republic. This procedure has been used with respect to a number of other agreements. It would be consistent, for example, with the procedure used in applying our Treaty of Friendhip, Commerce, and Navigation and our Double Tax Convention with the Federal Republic to West Berlin. And we have been informed that it would be acceptable to the British and French as our occupation partners in West Berlin, as well as to the German Federal Government and the Berlin authorities.

Senator PASTORE. Thank you. Now, Congressman Cole.

Representative COLE. I note from Mr. Hall's statement that West Berlin is ready to pay the entire cost of this research reactor, which is somewhat at variance with the policy we have established in this regard with other countries. Can you explain how that comes about?

Mr. HALL. On the basis of information that is available to me it is their desire to go forward this way. As I understand it, the West Berlin Senat has acquired funds to purchase the reactor outright. With reference to our other policy in connection with the Presidential offer, of course, West Germany is participating in that. As far as I am aware they have not raised the question as to whether West Germany should participate and up to this point it has been a completely commercial transaction between the North American Aviation and the West Berlin authorities.

Representative COLE. I think you have answered it. At least you have suggested to my mind an answer or an explanation. The policy of our assistance in research reactors with foreign countries is limited to only one reactor per country.

Mr. HALL. Yes, sir.

Representative COLE. Since West Germany is in control or will be in control of the reactor for West Berlin and since West Germany has already benefited from that Presidential offer, then the offer would not be available to a second reactor; the second one being located in West Berlin.

Mr. HALL. I presume that is the conclusion to draw.

Representative COLE. Is there any significance in the striking difference in the strength of these two reactors: the one in East Germany by the Russians of 2,500 kilowatts and the research reactor in West Berlin of 50 kilowatts?

Mr. HALL. No, sir. The record will indicate earlier the authorities were thinking about a larger reactor. As far as I am aware it is

related purely to the type of reactor they eventually decided upon and also the amount of money involved. I rather expect that this reactor would cost less than the swimming-pool reactor which would have been a larger reactor and which they had discussed earlier.

Representative COLE. As I get it, one of the strongest arguments in support of a reactor in West Berlin is the psychological effect it may have and it would seem to me that it would be doing violence to the potential good, from a psychological standpoint, if the Russians were able to publicize the fact that they had given a research reactor to the part of Germany under Russian control which was 50 times the size of the reactor that the United States is cooperating with in West Berlin.

Mr. HALL. Yes. As to the exact status of the reactor in Dresden I have very little information other than what the State Department has told us. The experience that we have heard about in other occupied zones is that the reactor offers of the Soviet Union are very, very slow in forthcoming. This is not completely responsive to your point, but I would rather expect there could be a 50-kilowatt reactor in Berlin before there is a reactor in Dresden. That is my guess based upon the experience in Yugoslavia. I believe over a year ago they tried to work out some deal. As far as I am aware there is no reactor in operation in Yugoslavia as yet. It is quite true this does suggest a competitive situation with the possibility of the larger reactor in Dresden.

Represntative COLE. On rereading your statement, Mr. Hall, I find the East Germany reactor is not being donated by Russia. Your statement indicates that East Germany is purchasing a reactor from Russia.

Mr. HALL. Yes, as far as we are aware.

Representative COLE. And under the proposal before us now, West Berlin would also purchase the reactor. Therefore, the question of the size of the reactor could not be argued as indicating the extent of help which the respective countries are giving to their respective German areas. That question of size is one that is determined by——

Mr. HALL. The purchaser.

Representative COLE. The German people themselves.

Again I raise the question of whether the bill should identify the area as Berlin or West Berlin?

Mr. LISLE. Sir, the bill defines "Berlin" for the meaning intended here in a manner which has been used in a great number of agreements and other documents as "those areas over which the Berlin Senat exercise jurisdiction (the United States, British, and French sectors)." I think it is desirable that the term "Berlin" be used here because from a purely conceptual symbolic point of view, Berlin is not divided. There is one Berlin which the Germans look forward to as their ultimate capital again. The Soviets have withdrawn from the structure which provided for a common government for Berlin. However, technically there is still the position maintained by the Senat that they are the government of Berlin and that it is the legal style under which they operate.

Representative COLE. Tell me a little about the Senat. How large is it? How many members does it have? How are they selected?

Mr. LISLE. In fact, the Senat is more comparable to a cabinet than to a legislative body. It has authorized members up to some 15. I

think there are 2 or 3 less than that. Each Senator has jurisdiction over an executive department such as finance. They meet collectively under the leadership of a governing mayor, at present, Dr. Suhr, who replaced the very famous Dr. Reuter, and they operate as a government council. This is superimposed upon a house of representatives which is the legislative body of Berlin.

Senator PASTORE. How is the mayor chosen?

Mr. LISLE. The mayor is chosen by the parties in the house of representatives. It follows the parallel of a cabinet system of government.

Senator PASTORE. Maybe I don't follow you, but we were talking about a senat. Now we are talking about a house of representatives. Do you have two branches?

Mr. LISLE. The senat is in one sense—it has this rather unusual situation. The predecessor of the Senat was in fact the upper house of a bicameral legislature. For practical purposes the Senat today is an executive body. It is a body which is very much in the nature of an ordinary European cabinet——

Senator PASTORE. Do you have another body known as the House of Representatives?

Mr. LISLE. There is another body known as the House of Representatives.

Senator PASTORE. How is it chosen?

Mr. LISLE. That is elected, sir.

Senator PASTORE. And the mayor is elected by the House of Representatives?

Mr. LISLE. Yes.

Representative COLE. And the members of the Senat are appointed.

Mr. LISLE. They are appointed.

Representative COLE. Who appoints them?

Mr. LISLE. They are chosen by the house.

Mr. KEARNEY. The provision is for the election of mayor and the senators are elected by the city council on the basic of a proposal by the governing mayor.

Mr. LISLE. In effect the procedure is like that by which a cabinet government is set up and it parallels the Federal Cabinet.

Chairman DURHAM. What is the population?

Mr. LISLE. The population of the western sector is something like 2.1 million and somewhat over 1 million in the eastern sector of Berlin.

Senator PASTORE. Did the West Berliners choose this process of administration or was it delegated to them by the commandants?

Mr. LISLE. They chose the process on the basis of a constitution which has been approved by the body of the commandants.

Senator PASTORE. Where do they get the revenue with which to buy this reactor?

Mr. LISLE. Their revenue is derived from two sources. The first is from the exercise of taxing power within Berlin and secondly through very extensive subventions and aids of various kinds provided by the Federal Republic of Germany. However, money is raised locally by taxation. Other money is raised in the Federal Republic. That is done in recognition of the unusual economic difficulties under which the city of Berlin operates and the need to provide certain assistance.

Representative COLE. On the question of financial support of West Berlin you should also include economic aid that comes directly from this country.

Mr. LISLE. Yes. Economic aid from this country generally for various projects, which today are limited in number and selected largely for their political and psychological importance, runs to something like $11.5 million a year.

Representative COLE. Then I judge from what you have just said that whatever economic aid may flow to West Berlin from this country would not be available for this project.

Mr. LISLE. It would not. Special projects are worked out with the government of Berlin and with the Government of the Federal Republic. All aid is earmarked for special projects.

Representative COLE. This bill would not preclude, however, the later inclusion of economic assistance with respect to this special project?

Mr. LISLE. No, sir; it would not.

Senator PASTORE. Coming back to the point that was raised by Mr. Cole in his question to Mr. Hall, Mr. Cole assumed and Mr. Hall assumed likewise that the reason the Berliners were paying for this was because the policy has been to grant only one research reactor on this 50–50 basis to each country. Now, is that the fact or are the West Berliners paying for this because they desire to do so? I think the record ought to be clear on that point. If that didn't come into it at all, the record ought to spell that out rather clearly.

Mr. HALL. The statement of the facts is as follows. As far as I am aware, the question of the United States financing assistance as a part of the Presidential offer was never raised with us by the West Berlin authorities.

Senator PASTORE. So it isn't actually carrying out the policy of giving only 1 to 1 nation. It is the fact that the question was never raised and they offered to pay for all of it and we accepted the offer on that basis. Is that the case or isn't it?

Mr. HALL. Yes, sir.

Senator PASTORE. I think the record ought to show that. Who will own this reactor?

Mr. LISLE. The reactor will be owned by the government of West Berlin and these institutions. The Free University and the Technical University are public institutions, the general government of which and I assume the property of which is in the hands of the Senat.

Senator PASTORE. Will the reactor itself be within the American Zone?

Mr. HALL. Yes, sir.

Mr. LISLE. The reactor; yes, sir.

Mr. HALL. As I understand it the zone is divided into three sectors. As my colleagues advised me earlier, it is the concept of a sector rather than the zone so the reactor will be located in the American sector. There are three sectors: the British, the French, and the American.

Chairman DURHAM. Do you know whether this request was first initiated by the scientific personnel of the universities or did it originate with the government body in control.

Mr. HALL. As I recall, Mr. Durham, it became rather merged in the thinking of the scientific community of West Berlin—or Berlin, rather—stimulated by the affirmative position that Ambassador

Conant had taken. To add to that, activity in West Germany was beginning to get started. The West German Government has under contract now three research reactors. So in tracing how the idea started in the very beginning, as I recall, it is rather complex. They wanted a reactor—"they" being the scientific community and these institutions. Ambassador Conant supported the idea.

Chairman DURHAM. Did he make any assessment of the quality of the technical personnel?

Mr. LISLE. Yes, sir. He thinks that the potential capacity of the scientific personnel in Berlin is very great and that they are fully prepared to take advantage of the opportunities this would provide.

Senator PASTORE. Speaking about the psychological effect of this, by our amending the 1954 law and giving entity to the West Berlin government to negotiate with us as a nation, psychologically what does that do with the Federal Republic of Germany?

Mr. LISLE. Well, sir, I don't think we——

Senator PASTORE. The minute we begin to recognize West Berlin as a separate nation under the intent and purposes of the 1954 amendment to the atomic energy law, doesn't that create a psychological atmosphere that is rather inconsistent with the political position we have taken heretofore?

Mr. LISLE. I don't think so, Mr. Chairman. What would be intended here would be that the amended agreement to the extent necessary would be made with the Government of the Federal Republic of Germany which under the existing arrangement handles the foreign affairs of Berlin. Berlin has no diplomatic representation abroad. The people in Berlin obtain West German passports. They receive the diplomatic protection of the Federal Republic and international agreements are made on behalf of Berlin by the Federal Republic. As a matter of fact, almost every treaty made today by the Federal Government contains a Berlin clause so that the treaty becomes effective in Berlin when ratified by the Senat and when it receives the approval, either express or implied, by the allied commandants.

Senator PASTORE. Then why couldn't this be a direct agreement with the Federal Republic of Germany with the approval of the commandants?

Mr. LISLE. This would be.

Senator PASTORE. Without amendment of the law?

Mr. HALL. Mr. Chairman, I think there are two points here. One is that on the basis of our review of the act, the Berlin concept did not seem to fall into the category of a nation. The proposed amendment provides a basis for us to enter into an arrangement with West Germany and at the same time——

Senator PASTORE. West Berlin.

Mr. HALL. No; with West Germany and the effect of this amendment would allow us—the West Germany bilateral would allow us to transfer fissionable material to West Berlin. In effect, in terms of the political impact of the amendment, I think that would be vitiated by the fact that we would still be dealing with West Germany. The amendment, in effect, would allow us to transfer fissionable material beyond West Germany to West Berlin.

Representative COLE. Our law authorizes agreements only with nations.

Mr. HALL. Yes, sir.

Representative COLE. West Berlin is not a part of the nation of West Germany.

Mr. HALL. Yes, sir.

Representative COLE. And therefore this changes——

Senator PASTORE. That is the question I raised. Are we prepared to make that admission?

Mr. LISLE. I think, Mr. Chairman, your idea arises from the rather unique situation of Berlin that has no parallel so far as I know. Every German would consider Berlin part of Germany.

Senator PASTORE. We have also considered Berlin part of West Germany. Now we are saying it isn't.

Mr. LISLE. Well, not quite.

Senator PASTORE. That is the point I make. We are talking about psychological reactions here. They work both ways.

Mr. LISLE. Berlin is not a Land of the Federal Republic. It is not one of the legal entities which, as such, is represented in the Bundesrat, which is somewhat comparable to our Senate, or in the Bundestag, by voting members. However, Berlin does send representatives to the Bundestag of the Federal Republic symbolizing the fact that Berlin is part of the Federal Republic. However, these representatives do not have the right to vote in the Bundestag.

Chairman DURHAM. Like Hawaii.

Mr. LISLE. Hawaii or Alaska.

Representative COLE. It seems to me the point the Senator has is rather important and it can be accommodated by rewording this resolution by authorizing the agreement with West Germany to also include that portion of Berlin which is under Allied or German jurisdiction.

Mr. HALL. There is another point involved. In order to conform with the guaranties in the statute, when we have a bilateral agreement we have to develop assurances on the part of the recipient state that they can carry out certain guaranties. If we have a bilateral agreement with West Germany, it would be impossible for West Germany to carry out the guaranties applying to West Berlin so this means that what we have to do—and that would be the effect of the proposed amendment—would be that there would be a bilateral agreement with West Germany and at the same time we would have, as a part of that arrangement in some fashion, an agreement on the part of the West Berlin authorities that they would carry out the guaranties required by the statute. That generally is how we would have to consummate a bilateral in order to conform to the statute. As I understand it the German Republic authorities have no authority over West Berlin.

Mr. LISLE. That is correct.

Representative COLE. That provision could be retained in any revision of this proposed bill.

Mr. HALL. I think probably it would be essential. It is a rather curious juridical problem because in effect our own authorities will be a part of the responsibile authorities in West Berlin that would be accepting the guaranties, but I think in order to conform with the statute this has to be done.

Senator PASTORE. As a matter of fact, our own forces would have absolute military power to turn this thing on or shut it off, regardless of any agreement, at any time they feel like it.

Mr. HALL. As I understand it, our commandant in the American sector has a complete voice not only in the affairs of the American sector, but he has a voice in affairs of the French and British sectors and to what extent the West Berlin Senat has authority depends upon our own authorities in West Berlin.

Senator PASTORE. Which raises a rather awkward situation that we are actually negotiating with a government that does not, in fact, exist. We have got to realize the fact that whatever they do they do with the approbation of the occupying forces, which are ours. The reason I am raising these questions is because I have got to answer these things on the floor, and you won't be there. I am anticipating what questions may be asked of us. You won't be there to help me.

Mr. LISLE. That situation is not unique in Berlin. It formerly existed with regard to the Federal Republic of Germany before the transfer of sovereignty on May 5, 1955. Before that time the three Allied Powers retained the ultimate authority in Germany under the occupation statute. As a matter of fact, in practice they did not exercise that, but they had these reserved powers. Despite that fact, each of the three occupying powers made a series of treaties with the Federal Republic of Germany. This was despite the fact that the ultimate sovereign authority was that of the three occupying powers.

Senator PASTORE. I see.

Chairman DURHAM. Would these bilateral agreements involve both West Berlin and Germany proper?

Mr. HALL. Mr. Durham, we already have a research——

Chairman DURHAM. I know you do.

Mr. HALL. Agreement. What we propose would probably be to have a separate agreement with West Germany which would accommodate this particular problem of West Berlin so the agreement that we would bring up to you for review—assuming the amendment goes into effect—would probably relate only to this particular problem before us.

Chairman DURHAM. Only West Berlin.

Mr. HALL. Yes, sir.

Mr. LISLE. But it would be an amendment to the agreement with the Federal Republic of Germany.

Chairman DURHAM. It would be.

Mr. LISLE. And would be negotiated with representatives of the Federal Government.

Chairman DURHAM. I don't see how you can get around it.

Mr. HALL. It would still require West Berlin authorities to assume supports of guaranties required by the statute, but among the authorities would be our commandant.

Chairman DURHAM. Both, of course, would have to sign the agreement. Would that be true?

Mr. HALL. Yes, sir.

Mr. LISLE. The agreement would be signed by a representative of the Federal Government. The guaranties would be signed by——

Mr. HALL. By the authorities in West Berlin.

Chairman DURHAM. It would be a combination agreement, then.

Representative COLE. I am wondering if this bill cannot be modified so as to clarify the situation and avoid the dilemma that Senator Pastore speaks of. I would ask your attention to the suggestion I

have to make. I am not sure that it is acceptable. It would be on line 7 so that it would read:

> The Commission is authorized to cooperate with the Federal Republic of Germany for and on behalf of Berlin, which for the purposes of this Act comprises those areas over which the Berlin Senat exercises jurisdiction. * * *

and then leave the balance of the bill as it is.

Mr. HALL. May I ask our legal counsel, Mr. Wells?

Senator PASTORE. Did you get that, Mr. Wells?

Mr. WELLS. Yes, I did, Senator Pastore. May I make just one comment, Mr. Cole? In drafting this particular language we had in mind that the cooperation itself would actually be with the entity of Berlin called the Senat, although the agreement would be made with the Federal Republic. Let me amplify that to this extent. As I understand it, the Senat would make a decision as to whether they would have a swimming-pool reactor or a boiling water reactor or something else. They would not need to consult with the Federal Republic of Germany. In all essential respects the cooperation is with Berlin although the agreement itself—for the psychological reasons which Senator Pastore mentioned and I think the things you had in mind, Congressman Cole—is with the Federal Republic of Germany on behalf of Berlin.

I would like to suggest that if the committee feels it is desirable to amend this language we simply bring the latter part of the section up to the top to say:

> An agreement for cooperation made by the Federal Republic of Germany on behalf of Berlin in accordance with section 123 may provide for cooperation with the city of Berlin.

The distinction I make is that we will not "cooperate" with the Federal Republic of Germany in this case, but will "cooperate" with Berlin pursuant to an agreement made on Berlin's behalf by the Federal Republic. My own observation, if I may make it, was that we had hoped to eliminate the psychological ill effects which the Senator mentioned by phrasing it in terms of cooperation with Berlin under an agreement made by the Federal Republic. Perhaps the latter should come first as a point of emphasis.

Senator PASTORE. Left the way it is, would it still satisfy Mr. Cole, or does Mr. Cole feel there is a legal impediment?

Representative COLE. No.

Senator PASTORE. If you switched the language around, you are actually using the same words and saying the same thing and carrying out the same intent.

Representative COLE. That is all I did—switch the words around.

Senator BRICKER. Who initiated this proposal—the city, the universities, or West Germany?

Mr. HALL. The West Berlin Senat, encouraged by the German Republic and supported by the American Ambassador. As I said earlier, it is a little difficult to determine just where the initiative started because they were all in agreement.

Representative VAN ZANDT. May I ask a question?

Senator PASTORE. Yes. Mr. Van Zandt.

Representative VAN ZANDT. At the Geneva Conference some years ago—and I am working from memory now—there was a very definite division within the ranks of the scientists in West Germany. I wonder if those wounds have been healed or if there is any solidarity there.

Mr. HALL. I think so. I think part of the problem—going back to 1955—was the internal problem of the Länder, as I think they are called, as against the Federal Government as to who should be responsible for the atomic energy development in West Germany. There was a great deal of feeling, particularly on the part of the scientists at universities, that there should be a more basic research approach and related to the universities. That, in part, has been dispelled by the fact that I believe Hamburg, Frankfurt, and Munich now will have research reactors and there has been established a Federal authority which gives some autonomy to the research being done in the various universities. As far as I am aware there is general harmony on this score now.

Representative VAN ZANDT. The elderly gentleman who was their No. 1 physicist, who was that? Is he still in the picture?

Mr. HALL. Heisenberg, I believe. Yes, sir. I haven't heard any complaints recently on that particular score.

Senator BRICKER. All of those bilaterals were with the Republic of West Germany?

Mr. HALL. Yes, sir.

Senator BRICKER. And they simply make them available to the various communities.

Mr. HALL. Yes, sir.

Senator BRICKER. Are they operated in cooperation with the universities in those localities?

Mr. HALL. Yes. As a matter of fact that activity presently going on in West Germany is fundamentally a university——

Senator BRICKER. Affair. That is what I thought. Are those reactors available to the university in West Berlin?

Mr. HALL. As far as I am aware; yes, sir.

Senator BRICKER. They are?

Mr. HALL. Yes, sir.

Representative COLE. You say this reactor will be located in the American sector. Does that mean it will be attached to and part of 1 of the 2 existing universities or will a new location and a new atomic center be developed?

Mr. HALL. As I understand it, a new center will be built, supervised, and made part of the framework my colleague has characterized.

Representative COLE. I have only one other question about the Senat. I am not quite clear on this. You said members of the Senat are chosen by members of the House of Representatives?

Mr. LISLE. Yes.

Representative COLE. Are they Members of the House of Representatives?

Mr. LISLE. That I don't know, sir. I think they are, according to the usual practice, but I must say I don't know. Some are, I know. I am not sure all are.

Mr. KEARNEY. The provision in the Berlin Constitution does not specify that they have to be.

Representative COLE. Then they may or may not be.

Mr. KEARNEY. Yes, sir.

Representative COLE. Another point I want to raise is this: The present law does not authorize the Commission to enter into any agreements for cooperation. This bill, as it is worded now, would be a departure from that principle and practice. The law says, "The

President may authorize the Commission" to enter into these agreements. I fancy you gentlemen would have no objection to having this bill reworded to conform with the other authority.

Mr. WELLS. I certainly wouldn't, Congressman Cole. As a matter of fact it is apparently inadvertent that it isn't in there.

Representative COLE. I am sure it was inadvertent, of course. May I invite your consideration to the suggested rewording I have jotted down here? I haven't thought about the title that has been given to it, but the body of the section would read:

> The President may authorize the Commission to enter into an agreement for cooperation with the Federal Republic of Germany in accordance with section 123, for and on behalf of Berlin, which for the purposes of this act * * *

and there are no changes for the rest of that first page. Then on the second page we would strike all of it from line 1 down to the proviso and retain the proviso. This would accomplish what you suggested, Mr. Wells, of bringing the end of the resolution up to the front part.

Mr. WELLS. I think that would be an improvement on it.

Senator PASTORE. Mr. Norris has raised another question on the proviso. He would put the word "the" before Berlin on the fourth line and put the word "Senat" after Berlin. What do you think of that, Mr. Cole?

Senator BRICKER. It is a question of whether the Senat acts on its own or acts on behalf of the legislative body.

Mr. LISLE. I believe it acts on behalf of Berlin. It would seem perhaps more appropriate to leave it the way it is.

Senator PASTORE. To leave it the way it is. All right.

Are there any further questions? Mr. Patterson?

Representative PATTERSON. No.

Senator PASTORE. Senator Bricker.

Senator BRICKER. There are already three reactors in West Germany?

Mr. HALL. No, sir. There will be.

Senator BRICKER. There are three bilaterals?

Mr. HALL. There is 1 bilateral which embraces the 3 reactors. Actually the present status is that I would expect it would be another year or so before the reactors will be constructed and completed.

Senator BRICKER. There is one constructed.

Mr. HALL. There is no reactor in operation now.

Senator BRICKER. None now.

Mr. HALL. I think in all spots the buildings are being constructed. They are being delivered by American firms, as I recall. I am not too familiar with the actual status, but there is no research reactor now operating in West Berlin. The reactors are under——

Senator BRICKER. I don't mean West Berlin.

Mr. HALL. West Germany.

Senator BRICKER. Those will be in connection with universities.

Mr. HALL. I believe all 3 are related to the universities or technical institutions at the 3 communities—Hamburg, Frankfurt, and Munich.

Senator BRICKER. All right.

Senator PASTORE. Is there anyone else in the room who desires to address himself to this particular issue?

Chairman DURHAM. Would you read the language you suggest again, Mr. Cole?

Representative COLE. Before we do that I want to just briefly have a bit of discussion as to the extent of this resolution which, as was indicated at the hearings, not only covers 1 research reactor and perhaps 2, but is sufficiently broad to include power reactor agreements. Is there any indication that West Berlin is looking toward an atomic power reactor?

Mr. HALL. As far as I am aware and the Commission, there is no immediate intention. There is no proposal for any other reactor. This point was discussed between the Department of State and ourselves. We felt that to limit the language of the amendment to a research reactor of this type would have the same type of political and psychological impact in that it would seem to discriminate against West Berlin. It is for that reason we are proposing the amendment providing the broad authority, although as a matter of policy I am not aware of any interest on the part of the West Berlin authorities for any activity to go beyond the present proposal for a research reactor. It establishes the authority, if such eventuality occurred wherein the West Berlin authorities decided for a larger reactor, there would be a legal basis. Naturally, then, we would have to entertain another amendment——

Representative COLE. Amendment to what?

Mr. HALL. To the existing bilateral before this could eventuate.

Senator BRICKER. Not the law.

Representative COLE. Not the law?

Mr. HALL. Yes.

Representative COLE. Can it be argued by anybody that the authority conveyed by this resolution is intended that whatever reactor may emanate from an agreement must be under Government sponsorship and ownership and operation?

Mr. HALL. I would not think so. I think all this does is to establish the legal framework by which a university or a company could operate with the normal type of Government approval which is required; the guaranties required by the recipient entity or nation.

Representative COLE. The reason I raised that question is that it has been brought to my attention that there are some countries with whom we have negotiated or are negotiating bilateral agreements who have the impression that it is an apparent policy of our Government that the reactors which result from the bilateral agreements must be publicly-owned reactors, which we know is not intended to be the fact. However, it seems to me that we should, in our negotiations between the Commission and foreign governments, whether by the Commission or state, make it perfectly clear that it is up to the local governments to determine which it shall be and that we are not advocating one way or another.

Mr. HALL. That is what we have done. In fact, we have included in every bilateral agreement a provision which is, in effect, a declaration of intent to encourage the industries of both the United States and the recipient country to cooperate in this field. We have tried to take an affirmative position. This affirmative position does exist in the present German research bilateral.

Representative COLE. Now I will read it again.

The President may authorize the Commission to enter into an agreement for cooperation with the Federal Republic of Germany in accordance with section 123, for and on behalf of Berlin, which for the purposes of this act comprises

those areas over which the Berlin Senat exercises jurisdiction (pursuant to sections 54, 57, 64, 82, 103, or 104) : *Provided,* That the guaranties required by section 123 shall be made by Berlin with the approval of the Allied Commandants.

Senator PASTORE. Tell us why you have changed it, Mr. Cole.

Representative COLE. Because of the questions that were raised by the chairman of the subcommittee which were so persuasive as to prompt me to concur with him and emphasize that we are not making fish or fowl in Berlin.

Senator PASTORE. I wasn't aiming for the compliment. I was trying to clarify why you have substituted the "President." It was so that it would be consistent and conform with our previous procedure.

Representative COLE. The law that authorizes the agreements for cooperation says:

The President may authorize the Commission to enter into * * *.

Senator PASTORE. That is right and it is in conformity with that language.

Chairman DURHAM. Nobody can authorize the Commission except the President.

Senatore PASTORE. I wanted it on the record.

Senator BRICKER. What is the status of the Communist reactor at the present time?

Mr. LISLE. Our information on the Communist reactor, sir, is based on Soviet sources which refer to an intention to have it operating during the spring of this year. These Communist sources show likewise certain photographs which would indicate there has been some measure of construction. Whether or not the reactor will actually operate or not we can't say. As Mr. Hall, I think, has pointed out, propaganda claims have not always been fulfilled.

Senator BRICKER. Do you have any idea of what that reactor will be like?

Mr. HALL. The information we have is that it will be a swimming-pool reactor, presumably of the general type at Geneva. The reactor on the basis of their own propaganda statements would be of a higher power than the reactor contemplated in West Berlin. It would be a research reactor, but a little larger reactor.

Senator BRICKER. Larger than those which are authorized in our bilaterals with West Germany?

Mr. HALL. As I recall, Senator, I think just about the same size. I believe the Munich reactor is around 2,000 or 2,500 kilowatts. As I recall the three reactors in West Germany will be more or less about the same size.

Senator BRICKER. This one will be smaller.

Mr. HALL. The one in Berlin will be smaller; yes.

Representative COLE. What is the type of those three in West Germany?

Mr. HALL. I will have to refresh my memory. Lou [Mr. Roddis], do you recall the three types in West Germany?

Senator PASTORE. Will you identify yourself?

Mr. RODDIS. I am Lou H. Roddis, Deputy Director of Reactor Development of the Atomic Energy Commission. The 21st semiannual report has that listed in it. I am trying to operate from memory now. As I recall there are two swimming pools of approximately 2,000-kilo-

watt thermal outfits and a water boiler of about the same size as the Berlin one; namely, about 50-kilowatt thermal.

Representative COLE. Those folks in our executive branch of Government whose duty it is to take advantage of psychological opportunities, it seems to me, could very well point to the fact that one reactor in Russian territory—East Germany—is the kind that they saw at Geneva. They have produced no new reactor concept whatever.

Mr. HALL. That is right.

Representative COLE. Whereas the ones in West Germany are not only the swimming-pool type, but so far as Central Europe is concerned, a new type—the boiling-water type.

Senator PASTORE. Are there any further questions?

Senator BRICKER. Will the Russian reactor be substantially the same as the reactor which was at Geneva?

Mr. HALL. That is our understanding. It is the swimming-pool reactor type; yes, sir.

Representative VAN ZANDT. What is the status of the Swiss reactor that we turned over to them?

Mr. HALL. As I understand, it has now been moved from Geneva to their proposed reactor research center near Zurich. The move took place literally within the past few months. They had a slowdown in getting the site prepared. I don't know whether the reactor is now operating or not, but it will be shortly on the basis of information that we have had this past week or 10 days. We were advised that the reactor probably will be in operation very shortly. The reactor has been moved from Geneva and is now near Zurich and its final location.

Mr. NORRIS. Appendix 14 of the 21st semiannual report, page 352, lists the 3 reactors for the Federal Republic of Germany: 1 is Munich, 1 is Hamburg, and 1 is the University of Frankfurt.

Senator PASTORE. All right, gentlemen. Thank you very much. The hearing is adjourned.

(Thereupon, at 11 o'clock a. m., the hearing was adjourned.)
